For the propagation or culture of particular plants, see AGRICULTURE, Part II. sect. 3. p. 288. and HUSBANDRY.

PROPER, something natural and essentially belonging to any thing.

PROPERTIUS (Sextus Aurelius), a celebrated Latin poet, born at Mevania, a city of Umbria, now called *Bevagna*, in the duchy of Spoleto. He went to Rome after the death of his father, a Roman knight, who had been put to death by order of Augustus, for having followed Antony's party during the triumvirate. Propertius in a short time acquired great reputation by his wit and abilities, and had a considerable share in the esteem of Mæcenas and Cornelius Gallus. He had also Ovid, Tibullus, Bassus, and the other ingenious men of his time, for his friends. He died at Rome 19 B. C. He is printed with almost all the editions of Tibullus and Catullus: but the best edition of him is that which was given separately by Janus Brouckhusius at Amsterdam, 1702, in 4to, and again in 1714, 4to. *cum curis secundis ejusdem*. We have four books of his *Elégies* or *Amours* with a lady called *Hostia*, or *Hostilia*, to whom he gave the name of *Cynthia*.

PROPERTY, in a general sense, is a particular virtue or quality which nature has bestowed on some things exclusive of all others: thus, colour is a property of light; extension, figure, divisibility, and impenetrability, are properties of body.

PROPERTY, in law, is described to be the highest right¹ which a person has or can have to any thing.

There is nothing which so generally strikes the imagination, and engages the affections of mankind, as the right of property; or that sole and despotic dominion which one man claims and exercises over certain external things of the world, in total exclusion of the right of any other individual in the universe. And yet there are very few that will give themselves the trouble to consider the original and foundation of this right. Pleased as we are with the possession, we seem afraid to look back to the means by which it was acquired, as if fearful of some defect in our title; or at best we rest satisfied with the decision of the laws in our favour, without examining the reason or authority upon which those laws have been built. We think it enough that our title is derived by the grant of the former proprietor, by descent from our ancestors, or by the last will and testament of the dying owner: not caring to reflect, that (accurately and strictly speaking) there is no foundation in nature or in natural law, why a set of words upon parchment should convey the dominion of land; why the son should have a right to exclude his fellow-creatures from

Proper
Property.

² The original foundation of the right to property not generally considered.

Property. a determinate spot of ground, because his father had done so before him; or why the occupier of a particular field or of a jewel, when lying on his death-bed and no longer able to maintain possession, should be entitled to tell the rest of the world which of them should enjoy it after him. These inquiries, it must be owned, would be useless and even troublesome in common life. It is well if the mass of mankind will obey the laws when made, without scrutinizing too nicely into the reasons of making them. But when law is to be considered not only as a matter of practice, but also as a rational science, it cannot be improper or useless to examine more deeply the rudiments and grounds of these positive constitutions of society.

3
This right
arises from
a divine
grant.

In the beginning of the world, we are informed by holy writ, that the all-bountiful Creator gave to man "dominion over all the earth; and over the fish of the sea, and over the fowl of the air, and over every living thing that moveth upon the earth." This is the only true and solid foundation of man's dominion over external things, whatever airy metaphysical notions may have been started by fanciful writers upon this subject. The earth, therefore, and all things therein, are the general property of all mankind, exclusive of other beings, from the immediate gift of the Creator. And, while the earth continued thinly inhabited, it is reasonable to suppose, that all was in common among them, and that every one took from the public stock to his own use such things as his immediate necessities required.

4
The state
of property
in the early
ages of the
world.

These general notions of property were then sufficient to answer all the purposes of human life; and might perhaps still have answered them, had it been possible for mankind to have remained in a state of primæval simplicity: as may be collected from the manners of many American nations, when first discovered by the Europeans; and from the ancient method of living among the first Europeans themselves, if we may credit either the memorial of them preserved in the golden age of the poets, or the uniform accounts given by historians of those times wherein *erant omnia communia et indivisa omnibus, veluti unum cunctis patrimonium esset*. Not that this communion of goods seems ever to have been applicable, even in the earliest ages, to aught but the *substance* of the thing; nor could it be extended to the *use* of it. For, by the law of nature and reason, he who first began to use it, acquired therein a kind of transient property, that lasted so long as he was using it, and no longer: or, to speak with greater precision, the *right* of possession continued for the same time only that the *act* of possession lasted. Thus the ground was in common, and no part of it was the permanent property of any man in particular; yet whoever was in the occupation of any determinate spot of it, for rest, for shade, or the like, acquired for the time a sort of ownership, from which it would have been unjust, and contrary to the law of nature, to have driven him by force; but the instant that he quitted the use or occupation of it, another might seize it without injustice. Thus also a vine or other tree might be said to be in common, as all were equally entitled to its produce; and yet any private individual might gain the sole property of the fruit, which he had gathered for his own repair. A doctrine well illustrated by Cicero, who compares the world to a great theatre, which is common to the public, and yet the place which any man has taken is for the time his own.

Blackst.
Comment.

But when mankind increased in number, craft, and ambition, it became necessary to entertain conceptions of more permanent dominion; and to appropriate to individuals, not the immediate *use* only, but the very *substance* of the thing to be used: otherwise innumerable tumults must have arisen, and the good order of the world been continually broken and disturbed, while a variety of persons were striving who should get the first occupation of the same thing, or disputing which of them had actually gained it. As human life also grew more and more refined, abundance of conveniences were devised to render it more easy, commodious, and agreeable; as habitations for shelter and safety, and raiment for warmth and decency. But no man would be at the trouble to provide either, so long as he had only an usufructuary property in them, which was to cease the instant that he quitted possession;—if, as soon as he walked out of his tent, or pulled off his garment, the next stranger who came by would have a right to inhabit the one and to wear the other. In case of habitations in particular, it was natural to observe, that even the brute creation, to whom every thing else was in common, maintained a permanent property in their dwellings, especially for the protection of their young; that the birds of the air had nests, and the beasts of the field had caverns, the invasion of which they esteemed a very flagrant injustice, and would sacrifice their lives to preserve them. Hence a property was soon established in every man's house and home-stall; which seem to have been originally mere temporary huts or moveable cabins, suited to the design of Providence for more speedily peopling the earth, and suited to the wandering life of their owners, before any extensive property in the soil or ground was established. And there can be no doubt, but that moveables of every kind became sooner appropriated than the permanent substantial soil: partly because they were more susceptible of a long occupancy, which might be continued for months together without any sensible interruption, and at length by usage ripen into an established right; but principally because few of them could be fit for use, till improved and meliorated by the bodily labour of the occupant; which bodily labour, bestowed upon any subject which before lay in common to all men, is universally allowed to give the fairest and most reasonable title to an exclusive property therein.

Property.
5
Rise of per-
manent
property in
various
things.

The article of food was a more immediate call, and therefore a more early consideration. Such as were not contented with the spontaneous product of the earth sought for a more solid refreshment in the flesh of beasts, which they obtained by hunting. But the frequent disappointments incident to that method of provision induced them to gather together such animals as were of a more tame and sequacious nature; and to establish a permanent property in their flocks and herds, in order to sustain themselves in a less precarious manner, partly by the milk of their dams, and partly by the flesh of the young. The support of these their cattle made the article of *water* also a very important point. And therefore the book of Genesis (the most venerable monument of antiquity, considered merely with a view to history) will furnish us with frequent instances of violent contentions concerning wells; the exclusive property of which appears to have been established in the first digger or occupant, even in such places where the ground and herbage remained.

6
In food
and other

articles.

7
Nature of
patriarchal
property.

Property. remained yet in common. Thus we find Abraham, who was but a sojourner, asserting his right to a well in the country of Abimelech, and exacting an oath for his security, "because he had digged that well." And Isaac, about 90 years afterwards, reclaimed this his father's property; and, after much contention with the Philistines, was suffered to enjoy it in peace.

All this while the soil and pasture of the earth remained still in common as before, and open to every occupant: except perhaps in the neighbourhood of towns, where the necessity of a sole and exclusive property in lands (for the sake of agriculture) was earlier felt, and therefore more readily complied with. Otherwise, when the multitude of men and cattle had consumed every convenience on one spot of ground, it was deemed a natural right to seize upon and occupy such other lands as would more easily supply their necessities. This practice is still retained among the wild and uncultivated nations that have never been formed into civil states, like the Tartars and others in the east; where the climate itself, and the boundless extent of their territory, conspire to retain them still in the same savage state of vagrant liberty, which was universal in the earliest ages, and which Tacitus informs us continued among the Germans till the decline of the Roman empire. We have also a striking example of the same kind in the history of Abraham and his nephew Lot. When their joint subsistence became so great, that pasture and other conveniences grew scarce, the natural consequence was, that a strife arose between their servants; so that it was no longer practicable to dwell together. This contention Abraham endeavoured to compose: "Let there be no strife, I pray thee, between thee and me. Is not the whole land before thee? Separate thyself, I pray thee, from me: If thou wilt take the left hand, then I will go to the right; or if thou depart to the right hand, then I will go to the left." This plainly implies an acknowledged right, in either, to occupy whatever ground he pleased, that was not pre-occupied by other tribes. "And Lot lifted up his eyes, and beheld all the plain of Jordan, that it was well watered everywhere, even as the garden of the Lord. Then Lot chose him all the plain of Jordan, and journeyed east; and Abraham dwelt in the land of Canaan."

Upon the same principle was founded the right of migration, or sending colonies to find out new habitations, when the mother-country was overcharged with inhabitants; which was practised as well by the Phœnicians and Greeks, as the Germans, Scythians, and other northern people. And, so long as it was confined to the stocking and cultivation of desert uninhabited countries, it kept strictly within the limits of the law of nature.

⁸ Necessity of property daily became more difficult to find out new spots to inhabit, without encroaching upon former occupants; and by constantly occupying the same individual spot, the fruits of the earth were consumed, and its spontaneous produce destroyed, without any provision for a future supply or succession. It therefore became necessary to pursue some regular method of providing a constant subsistence; and this necessity produced, or at least promoted and encouraged, the art of agriculture. And the art of agriculture, by a regular connection and consequence, introduced and established the idea

of a more permanent property in the soil than had hitherto been received and adopted. It was clear that the earth would not produce her fruits in sufficient quantities without the assistance of tillage; but who would be at the pains of tilling it, if another might watch an opportunity to seize upon and enjoy the product of his industry, art, and labour? Had not therefore a separate property in lands, as well as moveables, been vested in some individuals, the world must have continued a forest, and men have been mere animals of prey; which, according to some philosophers, is the genuine state of nature. Whereas now (so graciously has Providence interwoven our duty and our happiness together) the result of this very necessity has been the ennobling of the human species, by giving it opportunities of improving its *rational* faculties, as well as of exerting its *natural*. Necessity begat property; and in order to insure that property, recourse was had to civil society, which brought along with it a long train of inseparable concomitants; states, government, laws, punishments, and the public exercise of religious duties. Thus connected together, it was found that a part only of society was sufficient to provide, by their manual labour, for the necessary subsistence of all; and leisure was given to others to cultivate the human mind, to invent useful arts, and to lay the foundations of science.

The only question remaining is, How this property became actually vested; or what it is that gave a man an exclusive right to retain in a permanent manner that specific land which before belonged generally to every body, but particularly to nobody? And as we before observed, that *occupancy* gave the right to the temporary use of the soil; so it is agreed upon all hands, that occupancy gave also the original right to the permanent property in the *substance* of the earth itself, which excludes every one else but the owner from the use of it. There is indeed some difference among the writers on natural law, concerning the reason why occupancy should convey this right, and invest one with this absolute property: Grotius and Puffendorf insisting, that this right of occupancy is founded upon a tacit and implied assent of all mankind, that the first occupant should become the owner; and Barbeyrac, Titius, Mr Locke, and others, holding, that there is no such implied assent, neither is it necessary that there should be; for that the very act of occupancy, alone, being a degree of bodily labour, is from a principle of natural justice, without any consent or compact, sufficient of itself to gain a title. A dispute that favours too much of nice and scholastic refinement. However, both sides agree in this, that occupancy is the thing by which the title was in fact originally gained; every man seizing to his own continued use such spots of ground as he found most agreeable to his own convenience, provided he found them unoccupied by any one else.

Property, both in lands and moveables, being thus originally acquired by the first taker, which amounts to a declaration, that he intends to appropriate the thing to his own use, it remains in him, by the principle of universal law, till such time as he does some other act which shows an intention to abandon it; for then it becomes, naturally speaking, *publici juris* once more, and is liable to be again appropriated.

Property. ted by the next occupant. So if one is possessed of a jewel, and casts it into the sea or a public highway, this is such an express dereliction, that a property will be vested in the first fortunate finder that shall seize it to his own use. But if he hides it privately in the earth, or other secret place, and it is discovered, the finder acquires no property therein; for the owner hath not by this act declared any intention to abandon it, but rather the contrary: and if he loses or drops it by accident, it cannot be collected from thence that he designed to quit the possession; and therefore in such case the property still remains in the loser, who may claim it again of the finder. And this, we may remember, is the doctrine of the English law with relation to *TREASURE-TROVE*.

But this method, of one man's abandoning his property, and another seizing the vacant possession, however well founded in theory, could not long subsist in fact. It was calculated merely for the rudiments of civil society, and necessarily ceased among the complicated interests and artificial refinements of polite and established governments. In these it was found, that what became inconvenient or useless to one man, was highly convenient and useful to another; who was ready to give in exchange for it some equivalent that was equally desirable to the former proprietor. This mutual convenience introduced commercial traffic, and the reciprocal transfer of property by sale, grant, or conveyance: which may be considered either as a continuance of the original possession which the first occupant had; or as an abandoning of the thing by the present owner, and an immediate successive occupancy of the same by the new proprietor. The voluntary dereliction of the owner, and delivering the possession to another individual, amount to a transfer of the property; the proprietor declaring his intention no longer to occupy the thing himself, but that his own right of occupancy shall be vested in the new acquirer. Or, taken in the other light, if I agree to part with an acre of my land to Titius, the deed of conveyance is an evidence of my intending to abandon the property; and Titius, being the only or first man acquainted with such my intention, immediately steps in and seizes the vacant possession: thus the consent expressed by the conveyance gives Titius a good right against me; and possession or occupancy confirms that right against all the world besides.

II
How it
goes on the
death of
the occu-
pant.

The most universal and effectual way of abandoning property is by the death of the occupant: when, both the actual possession and intention of keeping possession ceasing, the property, which is founded upon such possession and intention, ought also to cease of course. For, naturally speaking, the instant a man ceases to be, he ceases to have any dominion: else, if he had a right to dispose of his acquisitions one moment beyond his life, he would also have a right to direct their disposal for a million of ages after him; which would be highly absurd and inconvenient (A). All property must therefore cease upon death, considering men as absolute individuals, and unconnected with ci-

VOL. XV.

vil society: for then, by the principles before established, the next immediate occupant would acquire a right in all that the deceased possessed. But as, under civilized governments, which are calculated for the peace of mankind, such a constitution would be productive of endless disturbances, the universal law of almost every nation (which is a kind of secondary law of nature) has either given the dying person a power of continuing his property, by disposing of his possessions by will; or, in case he neglects to dispose of it, or is not permitted to make any disposition at all, the municipal law of the country then steps in, and declares who shall be the successor, representative, or heir of the deceased; that is, who alone shall have a right to enter upon this vacant possession, in order to avoid that confusion which its becoming again common would occasion. And further, in case no testament be permitted by the law, or none be made, and no heir can be found so qualified as the law requires, still, to prevent the robust title of *occupancy* from again taking place, the doctrine of escheats is adopted in almost every country; whereby the sovereign of the state, and those who claim under his authority, are the ultimate heirs, and succeed to those inheritances to which no other title can be formed.

The right of inheritance, or descent to the children and relations of the deceased, seems to have been allowed much earlier than the right of devising by testament. We are apt to conceive at the first view that it has nature on its side; yet we often mistake for nature what we find established by long and inveterate custom. It is certainly a wise and effectual, but clearly a political, establishment; since the permanent right of property, vested in the ancestor himself, was no *natural*, but merely a *civil*, right. It is true, that the transmission of one's possessions to posterity has an evident tendency to make a man a good citizen and a useful member of society: it sets the passions on the side of duty, and prompts a man to deserve well of the public, when he is sure that the reward of his services will not die with himself, but be transmitted to those with whom he is connected by the dearest and most tender affections. Yet, reasonable as this foundation of the right of inheritance may seem, it is probable that its immediate original arose not from speculations altogether so delicate and refined, and, if not from fortuitous circumstances, at least from a plainer and more simple principle. A man's children or nearest relations are usually about him on his death-bed, and are the earliest witnesses of his decease. They became therefore generally the next immediate occupants, till at length in process of time this frequent usage ripened into general law. And therefore also in the earliest ages, on failure of children, a man's servants born under his roof were allowed to be his heirs; being immediately on the spot when he died. For we find the old patriarch Abraham expressly declaring, that "since God had given him no seed, his steward Eliezer, one born in his house, was his heir."

Property.

is

Last will
or testa-
ments.

were useless and unknown; and when it became inheritable, the inheritance was long indefeasible, and the children or heirs at law were incapable of exclusion by will. Till at length it was found, that so strict a rule of inheritance made heirs disobedient and headstrong, defrauded creditors of their just debts, and prevented many provident fathers from dividing or charging their estates as the exigence of their families required. This introduced pretty generally the right of disposing of one's property, or a part of it, by *testament*; that is, by written or oral instructions properly *witnessed* and authenticated, according to the *pleasure* of the deceased; which we therefore emphatically style his *will*. This was established in some countries much later than in others. In England, till modern times, a man could only dispose of one-third of his moveables from his wife and children; and, in general, no will was permitted of lands till the reign of Henry VIII. and then only of a certain portion; for it was not till after the Restoration that the power of devising real property became so universal as at present.

Are crea-
tures of the
civil or
municipal
laws,
Blackst.
Comment.

Wills, therefore, and testaments, rights of inheritance, and successions, are all of them creatures of the civil or municipal laws, and accordingly are in all respects regulated by them; every distinct country having different ceremonies and requisites to make a testament completely valid; neither does any thing vary more than the right of inheritance under different national establishments. In England particularly, this diversity is carried to such a length, as if it had been meant to point out the power of the laws in regulating the succession to property, and how futile every claim must be that has not its foundation in the positive rules of the state. In personal estates, the father may succeed to his children; in landed property, he never can be their immediate heir by any the remotest possibility: in general, only the eldest son, in some places only the youngest, in others all the sons together, have a right to succeed to the inheritance: In real estates, males are preferred to females, and the eldest male will usually exclude the rest; in the division of personal estates, the females of equal degree are admitted together with the males, and no right of primogeniture is allowed.

15
Scruples
respecting
heritable
property
removed.

This one consideration may help to remove the scruples of many well-meaning persons, who set up a mistaken conscience in opposition to the rules of law. If a man disinherits his son, by a will duly executed, and leaves his estate to a stranger, there are many who consider this proceeding as contrary to natural justice; while others so scrupulously adhere to the supposed intention of the dead, that if a will of lands be attested by only *two* witnesses instead of *three*, which the law requires, they are apt to imagine that the heir is bound in conscience to relinquish his title to the devisee. But both of them certainly proceed upon very erroneous principles: as if, on the one hand, the son had by nature a right to succeed to his father's lands: or as if, on the other hand, the owner was by nature entitled to direct the succession of his property after his own decease. Whereas the law of nature suggests, that on the death of the possessor, the estate should again become common, and be open to the next occupant, unless otherwise ordered, for the sake of civil

peace, by the positive law of society. The positive law of society, which is the municipal laws of England and Scotland, directs it to vest in such person as the last proprietor shall by will, attended with certain requisites, appoint; and, in defect of such appointment, to go to some particular person, who, from the result of certain local constitutions, appears to be the heir at law. Hence it follows, that, where the appointment is regularly made, there cannot be a shadow of right in any one but the person appointed: and, where the necessary requisites are omitted, the right of the heir is equally strong and built upon as solid a foundation, as the right of the devisee would have been, supposing such requisites were observed.

But, after all, there are some few things, which, notwithstanding the general introduction and continuance of property, must still unavoidably remain in common; being such wherein nothing but an usufructuary property is capable of being had: and therefore they still belong to the first occupant, during the time he holds possession of them, and no longer. Such (among others) are the elements of light, air, and water; which a man may occupy by means of his windows, his gardens, his mills, and other conveniences: such also are the generality of those animals which are said to be *feræ naturæ*, or of a wild and untameable disposition; which any man may seize upon and keep for his own use or pleasure. All these things, so long as they remain in possession, every man has a right to enjoy without disturbance; but if once they escape from his custody, or he voluntarily abandons the use of them, they return to the common stock, and any other man has an equal right to seize and enjoy them afterwards.

Again, there are other things in which a permanent property may subsist, not only as to the temporary use, but also the solid substance; and which yet would be frequently found without a proprietor, had not the wisdom of the law provided a remedy to obviate this inconvenience. Such are forests and other waste grounds, which were omitted to be appropriated in the general distribution of lands: such also are wrecks, estrays, and that species of wild animals, which the arbitrary constitutions of positive law have distinguished from the rest by the well-known appellation of *game*. With regard to these and some others, as disturbances and quarrels would frequently arise among individuals contending about the acquisition of this species of property by first occupancy, the law has therefore wisely cut up the root of dissension, by vesting the things themselves in the sovereign of the state; or else in his representatives appointed and authorised by him, being usually the lords of manors. And thus the legislature has universally promoted the grand ends of civil society, the peace and security of individuals, by steadily pursuing that wise and orderly maxim, of assigning to every thing capable of ownership a legal and determinate owner.

In this age of paradox and innovation, much has been said of *liberty* and *equality*; and some few have contended for an equalization of property. One of the wildest declaimers on this subject, who is for abolishing property altogether, has (inadvertently we suppose) given a complete confutation, not only of his own arguments, but also of the arguments of all who have

The rea-
soning of
those who
contend for
an equali-
zation of
property.

Property, have written, or, we think, can write, on the same side of the question. After labouring to prove that it is gross injustice in any man to retain more than is absolutely necessary to supply him with food, cloathes, and shelter, this zealous reformer states an objection to his theory, arising from the well-known allurements of sloth, which, if the accumulation of property were not permitted, would banish industry from the whole world. The objection he urges fairly, and answers it thus: "It may be observed, that the equality for which we are pleading is an equality that would succeed to a state of great intellectual improvement. So bold a revolution cannot take place in human affairs, till the general mind has been highly cultivated. The present age of mankind is greatly enlightened; but it is to be feared is not yet enlightened enough. Hasty and undigested tumults may take place, under the idea of an equalization of property; but it is only a calm and clear conviction of justice, of justice mutually to be rendered and received, of happiness to be produced by the *desertion of our most rooted habits*, that can introduce an invariable system of this sort. Attempts without this preparation will be productive only of confusion. Their effect will be momentary, and a new and more barbarous inequality will succeed. Each man with unaltered appetite will watch his opportunity to gratify his love of power, or his love of distinction, by usurping on his inattentive neighbours."

19
The effect
of igno-
rance of
human na-
ture.

These are just observations, and such as we have often made to ourselves on the various proposed reformation of government. The illumination which the author requires before he would introduce his abolition of property, would constitute men more than angels; for to be under the influence of no passion or appetite, and to be guided in every action by unmixed benevolence and pure intellect, is a degree of perfection which we can attribute to no being inferior to God. But it is the object of the greater part of this writer's book to prove that all men must arrive at such perfection before his ideal republic can contribute to their happiness; and therefore every one who is conscious of being at any time swayed by passion, and who feels that he is more attached to his wife or children than to strangers, will look without envy to the present inequalities of property and power, if he be an intelligent disciple of Mr Godwin.

Literary PROPERTY. See *COPY-Right*.

1
Definition. PROPHECY is a word derived from *προφητεια*, and in its original import signifies the prediction of future events.

2
Prophecy proves a supernatural communion with the Deity. As God alone can perceive with certainty the future actions of free agents, and the remote consequences of those laws of nature which he himself established, prophecy, when clearly fulfilled, affords the most convincing evidence of an intimate and supernatural communion between God and the person who uttered the prediction. Together with the power of working miracles, it is indeed the only evidence which can be given of such a communion. Hence among the professors of every religious system, except that which is called the religion of nature, there have been numberless pretenders to the gift of prophecy. The pagan nations of antiquity had their oracles, augurs, and soothsayers. Modern idolaters have their necromancers and divines and the

3
The professors of all religions have pretended to it.

Jews, Christians, and Mahometans, have their seers and Prophecy. prophets.

The ill-founded pretensions of paganism, ancient and modern, have been exposed under various articles of this work. See DIVINATION, MAGIC, NECROMANCY, and MYTHOLOGY. And the claims of the Arabian impostor are examined under the articles ALCO-RAN and MAHOMETANISM; so that at present we have only to consider the use, intent, and truth, of the Jewish and Christian prophecies.

Previous to our entering on this investigation it may be proper to observe, that in the Scriptures of the Old and New Testaments, the signification of the word prophecy is not always confined to the foretelling of future events. In several instances it is of the same import with preaching, and denotes the faculty of illustrating and applying to present practical purposes the doctrines of prior revelation. Thus in Nehemiah it is said, "thou hast appointed prophets to preach *;" and whoever speaketh unto men to edification, and exhortation and comfort, is by St Paul called a *prophet*†. Hence it was that there were schools of prophets in Israel, where young men were instructed in the truths of religion, and fitted to exhort and comfort the people.

In this article, however, it is chiefly of importance to confine ourselves to that kind of prophecy, which, in declaring truths either past, present, or future, required the immediate inspiration of God.

Every one who looks into the history of the world must observe that the minds of men have from the beginning been gradually opened by a train of events still improving upon, and adding light to each other; as that of each individual is, by proceeding from the first elements and seeds of science, to more enlarged views, and a still higher growth. Mankind neither are nor ever have been capable of entering into the depths of knowledge at once; of receiving a whole system of natural or moral truths together; but must be let into them by degrees, and have them communicated by little and little, as they are able to bear it. That this is the case with respect to human science, is a fact which cannot be questioned; and there is as little room to question it with respect to the progress of religious knowledge among men either taken collectively or in each individual. Why the case is thus in both, why all are not adult at once in body and mind, is a question which the religion of nature is equally called upon with revelation to answer. The fact may not be easily accounted for, but the reality of it is incontrovertible.

Accordingly, the great object of the several revelations recorded in the Old Testament was evidently to keep alive a sense of religion in the minds of men, and to train them by degrees for the reception of those simple but sublime truths by which they were to be saved. The notions which the early descendants of Adam entertained of the Supreme Being, and of the relation in which they stood to him, were probably very gross; and we see them gradually refined by a series of revelations or prophecies, each in succession more explicit than that by which it was preceded, till the advent of Him who was the way, the truth, and the life, and who brought to light life and immortality.

When a revelation was made of any important truth, the grounds of which the mind of man has not faculties

4
The word in Scripture has various meanings.

* Ch. vi. v. 7.
† 1 Cor. ch. xiv. v. 3.

5
Science and religion gradually acquired.

5
The revelation of the Old Testament gradual.

Prophecy. ties to comprehend, that revelation, though undoubtedly a prophecy, must have been so far from confirming the truth of revealed religion in general, that it could not gain credit itself, but by some extrinsic evidence that it came indeed from God. Hence we find Moses, after it was revealed to him from the burning bush that he should deliver his countrymen from Egyptian bondage, replying, "Behold, they will not believe me, nor hearken to my voice; for they will say, the Lord hath not appeared unto thee." This revelation certainly constituted him a prophet to Israel; and there cannot be a doubt but that he perfectly knew the divine source from which he received it: but he very naturally and reasonably concluded, that the children of Israel would not believe that the Lord had appeared to him, unless he could give them some other proof of this preternatural appearance than his own simple affirmation of its reality. This proof he was immediately enabled to give, by having conferred upon him the power of working miracles in confirmation of his prophecy. Again, when Gideon was called to the deliverance of Israel, the angel of the Lord came and said unto him, "The Lord is with thee, thou mighty man of valour: go in this thy might, and thou shalt save Israel from the hand of the Midianites. Have not I sent thee?" Here was a prophecy delivered by the angel of the Lord to encourage Gideon's undertaking: but he, being probably afraid of some illusion of sense or imagination, demanded a sign that he was really an angel who talked with him. A sign is accordingly given him, a miraculous sign, with which he is satisfied, and undertakes the work appointed him.

From these and many similar transactions recorded in the Old Testament, it appears that prophecy was never intended as evidence of an original revelation. It is indeed, by its very nature, totally unfit for such a purpose; because it is impossible, without some extrinsic proof of its divine origin, to know whether any prophecy be true or false, till the era arrive at which it ought to be fulfilled. When it is fulfilled, it affords complete evidence that he who uttered it spake by the spirit of God, and that the doctrines which he taught of a religious nature, were all either dictated by the same spirit, or at least are true, and calculated to direct mankind in the way of their duty.

The prophecies vouchsafed to the patriarchs in the most early periods of the world, were all intended to keep alive in their minds a sense of religion, and to direct their views to the future completion of that first and greatest prophecy which was made to Adam immediately on his fall: but in order to secure credit to those prophecies themselves, they were always accompanied by some miraculous sign that they were indeed given by the God of truth, and not the delusions of fanaticism or hypocrisy. Prophecy, in the proper sense of the word, commenced with the fall; and the first instance of it is implied in the sentence denounced upon the original deceiver of mankind; "I will put enmity between thee and the woman, and between thy seed and her seed: It shall bruise thy head, and thou shalt bruise his heel."

This prophecy, though one of the most important that ever was delivered, when considered by itself, is exceedingly obscure. That Adam should have understood it, as some of his degenerate sons have pretended

to do, in a literal sense, is absolutely impossible. He knew well that it was the great God of heaven and earth who was speaking, and that such a being was incapable of trifling with the wretchedness of his fallen creature. The sentence denounced upon himself and his wife was awful and severe. The woman was doomed to sorrow in conception; the man to sorrow and travel all the days of his life. The ground was cursed for his sake; and the end of the judgment was, "Dust thou art, and to dust thou shalt return." Had our first parents been thus left, they must have looked upon themselves as rejected by their Maker, delivered up to trouble and sorrow in the world, and as having no hope in any other. With such impressions on their minds they could have retained no sense of religion; for religion, when unaccompanied by hope, is a state of frenzy and distraction: yet it is certain that they could have no hope from any thing expressly recorded by Moses, except what they might draw from this sentence passed on their deceiver. Let us then endeavour to ascertain what consolation it could afford them.

At that awful juncture, they must have been sensible that their fall was the victory of the serpent, whom by experience they had found to be an enemy to God and to man. It could not therefore but be some comfort to them to hear this enemy first condemned, and to see that, however he had prevailed against them, he had gained no victory over their Maker. By his condemnation they were secured from thinking that there was any malignant being equal to the Creator in power and dominion; an opinion which, through the prevalency of evil, gained ground in after times, and was destructive of all true religion. The belief of God's supreme dominion being thus preserved, it was still necessary to give them such hopes as might induce them to love as well as to fear him; and these they could not but conceive when they heard from the mouth of their Creator and Judge, that the serpent's victory was not complete even over themselves; that they and their posterity should be enabled to contest his empire; and that though they were to suffer much in the struggle, they should yet finally prevail, bruise the serpent's head, and deliver themselves from his power and dominion.

This prophecy therefore was to our first parents a light shining in a dark place. All that they could certainly conclude from it was, that their case was not desperate; that some remedy, some deliverance from the evil they were under, would in time appear; but *when* or *where*, or by *what means* they were to be delivered, they could not possibly understand, unless the matter was further revealed to them, as probably it was at the institution of sacrifice (see SACRIFICE). Obscure, however, as this promise or prophecy was, it served after the fall as a foundation for religion, and trust and confidence towards God in hopes of deliverance in time from the evils of disobedience: and this appears to have been the sole purpose for which it was given, and not, as some well-meaning, though weak advocates for Christianity have imagined, as a prediction pointing *directly* to the cross of Christ.

As this prophecy was the first, so is it the only considerable one in which we have any concern from the creation to the days of Noah. It was proportioned to the then wants and necessities of the world, and was the grand charter of God's mercy after the fall. Nature

Prophecy.

Prophecy. had no certain help for sinners; her rights were lost with her innocence. It was therefore necessary either to destroy the offenders, or to raise them to a capacity of salvation, by giving them such hopes as might enable them to exercise a reasonable religion. So far the light of this prophecy extended. By what *means* God intended to work their salvation, he did not expressly declare: and who has a right to complain that he did not, or to prescribe to him rules in dispensing his mercy to the children of men?

II
The curse removed from the ground.

* Use and Intent of Prophecy.

Upon the hopes of mercy which this prophecy gives in very general terms, mankind rested till the birth of Noah. At that period a new prophecy was delivered by Lamech, who foretels that his son should comfort them concerning the work and toil of their hands, "because of the *earth which the Lord had cursed*." We are to remember that the curse pronounced upon the earth was part of the sentence passed upon our first parents; and when that part was remitted, if it ever was remitted, mankind would acquire new and more lively hopes that in God's good time they should be freed from the whole. But it has been shown by bishop Sherlock*, that this declaration of Lamech's was a prediction, that during the life of his son the curse should be taken off from the earth: and the same prelate has proved with great periphrasis, and in the most satisfactory manner, that this happy revolution actually took place after the flood. The limits prescribed to an article of this kind will not permit us even to abridge his arguments. We shall only observe, that the truth of his conclusion is manifest from the very words of scripture; for when God informs Noah of his design to destroy the world, he adds, "But with thee will I establish my covenant:" and as soon as the deluge was over, he declared that he "would not again curse the ground any more for man's sake; but that while the earth should remain, seed-time and harvest, and cold and heat, and summer and winter, and day and night, should not cease." From this last declaration it is apparent that a curse *had* been on the earth, and that seed-time and harvest had often failed; that the curse was now taken off; and that in consequence of this covenant, as it is called, with Noah and his seed and with every living creature, mankind should not henceforth be subject to toil so severe and so generally fruitless.

12
A future life not then explicitly revealed.

It may seem surprising perhaps to some, that after so great a revolution in the world as the deluge made, God should say nothing to the remnant of mankind of the punishments and rewards of another life, but should make a new covenant with them relating merely to fruitful seasons and the blessings of the earth. But in the scriptures we see plainly a gradual working of providence towards the redemption of the world from the curse of the fall; that the temporal blessings were first restored as an earnest and pledge of better things to follow; and that the covenant given to Noah had, strictly speaking, nothing to do with the hopes of futurity, which were reserved to be the matter of another covenant, in another age, and to be revealed by him, whose province it was to "bring life and immortality to light through the gospel." But if Noah and his forefathers expected deliverance from the whole curse of the fall, the actual deliverance from one part of it was a very good pledge of a further deliverance to be expected in time. Man himself was cursed as well as the ground; he was doomed to dust; and fruitful seasons

are but a small relief, compared to the greatness of his loss. But when fruitful seasons came, and one part of the curse was evidently abated, it gave great assurance that the other should not last forever, but that by some means, still unknown to them, they should be freed from the whole, and finally bruise the serpent's head, who, at the deluge, had so severely bruised man's heel.

Upon this assurance mankind rested for some generations, and practised, as we have every reason to believe, a rational worship to the one God of the universe. At last, however, idolatry was by some means or other introduced (see *POLYTHEISM*), and spread so universally through the world, that true religion would in all probability have entirely failed, had not God visibly interposed to preserve such a sense of it as was necessary for the accomplishment of his great design to restore mankind. This he did by calling Abraham from amidst his idolatrous kindred, and renewing to him the word of prophecy: "Get thee out of thy country (said he), and from thy kindred, and from thy father's house, unto a land that I will shew thee. And I will make of thee a great nation, and I will bless thee and make thy name great; and thou shalt be a blessing. And I will bless them that bless thee, and curse them that curse thee; and in thee shall all the families of the earth be blessed." These magnificent promises are several times repeated to the father of the faithful with additional circumstances of great importance, such as, "that he should be multiplied exceedingly; that he should be a father of many nations; that kings should come out of him;" and above all, that God would establish an *everlasting covenant* with him and his seed, to give him and them all the land of Canaan for an *everlasting possession*, and to be *their God*."

Upon such of these promises as relate to temporal blessings we need not dwell. They are much of the same nature with those which had been given before to Lamech, Noah, Shem, and Japheth; and all the world knows how amply and literally they have been fulfilled. There was however so little probability in nature of their accomplishment at the time when they were made, that we find the patriarch asking "Whereby he should *know* † that he should inherit such an extent of country?" And as the promises that he should inherit it were meant to be a foundation for religion and confidence in God, a miraculous sign was given him, that they came indeed from the spirit of truth. This removed from his mind every doubt, and made him give the fullest credit, not only to them, but also to that other promise, "that in his seed should all the nations of the earth be blessed."

What distinct notion he had of this blessing, or in what manner he hoped it should be effected, we cannot pretend to say. "But that he understood it to be a promise of restoring mankind, and delivering them from the remaining curse of the fall, there can be no doubt. He knew that death had entered by sin; he knew that God had promised victory and redemption to the seed of the woman. Upon the hopes of this restoration the religion of his ancestors was founded; and when God, from whom this blessing on all men was expected, did expressly promise a blessing on all men, and in this promise founded his everlasting covenant—what could Abraham else expect but the completion in his seed of that ancient promise and prophecy concerning the victory

Prophecy.

13
Promise to Abraham.

† Genesis. xv. 8. &c.

Prophecy. to be obtained by the woman's seed? The curse of the ground was expiated in the flood, and the earth restored with a blessing, which was the foundation of the temporal covenant with Noah; a large share of which God expressly grants to Abraham and his posterity particularly, together with a promise to bring, by their means, a new and further blessing upon the whole race of men. If we lay these things to heart, we cannot suppose that less could be expected from the new promise or prophecy given to Abraham than a deliverance from that part of the curse still remaining on man: *Dust thou art, and to dust thou shalt return.* In virtue of this covenant Abraham and his posterity had reason to expect that the time would come when man should be called from his dust again. For this expectation they had his assurance who gave the covenant, that he would be their God forever. Well might our Saviour then tell the sons of Abraham, that even Moses at the bush showed the resurrection of the dead, when he called the Lord the God of Abraham, and the God of Isaac, and the God of Jacob *."

* Sherlock's Use and Intent of Prophecy.

14 To Isaac and Jacob.

15 The law of Moses and the succeeding prophets.

These promises made to Abraham were renewed to Isaac and Jacob; to the last of whom it was revealed, not only that all the nations of the earth should be blessed in his seed, but that the blessing should spring from his son Judah. It is, however, by no means evident that any one of those patriarchs knew precisely by what means (A) the curse of the fall was to be entirely removed, and all men called from their dust again. It was enough that they were convinced of the fact in general terms, since such conviction was a sufficient foundation of a rational religion; and the descendants of Abraham had no other foundation upon which to rest their hopes, and pay a cheerful worship to the God of their fathers, till the giving of the law to Moses. Then indeed they were incorporated into a society with municipal laws of their own and placed under a theocratic government; the temporal promises made to their fathers were amply fulfilled; religion was maintained among them by rewards and punishments equally distributed in this world (see THEOLOGY): and a series of prophets succeeding one another pointed out with greater and greater clearness, as the fulness of time approached, the person who was to redeem mankind from the power of death; by what means he was to work that great redemption, and at what precise period he was to make his appearance in the world. By these supernatural interpositions of divine providence, the principles of pure theism and the practice of true religion were preserved among the children of Israel, when all other nations were sunk in the grossest idolatry, and wallowed in the most abominable vices; when the far-famed Egyptians, Greeks, and Romans, fell down with ado-

ration to stocks and stones and the vilest reptiles; and when they had no well grounded hope of another life, and were in fact without God in the world. **Prophecy.**

From this short deduction, we think ourselves intitled to conclude, that the *primary* use and intent of prophecy, under the various dispensations of the Old Testament, was not, as is too often supposed, to establish the divine mission of Jesus Christ, but to keep alive in the minds of those to whom it was given, a sense of religion, and a hope of future deliverance from the curse of the fall. It was, in the expressive language of St Peter, "a light that shone in a dark place, unto which men did well to take heed until the day dawned and the day-star arose in their hearts." But though this was certainly the original intent of prophecy (for Christ, had he never been foretold, would have proved himself to be the Son of God with power by his astonishing miracles, and his resurrection from the dead), yet it cannot be denied, that a long series of prophecies, given in different and far distant ages, and having all their completion in the life, death, and resurrection, of Jesus, concur very forcibly with the evidence of miracles to prove that he was the seed of the woman ordained to bruise the head of the serpent, and restore man to his forfeited inheritance. To the Jews the force of this evidence must have been equal, if not superior, to that of miracles themselves; and therefore we find the Apostles and first preachers of the gospel, in their addresses to them, constantly appealing to the law and the prophets, whilst they urged upon the Gentiles the evidence of miracles.

In order to form a right judgment of the argument for the truth of Christianity drawn from the sure word of prophecy, we must not consider the prophecies given in the Old Testament as so many *predictions* only independent of each other; for if we do, we shall totally lose sight of the purpose for which they were originally given, and shall never be able to satisfy ourselves when confronted by the objections of unbelievers. It is easy for men of leisure and tolerable parts to find difficulties in particular predictions, and in the application of them made by writers, who lived many hundred years ago, and who had many ancient books and records of the Jewish church, from which they drew many passages, and perhaps some prophecies; which books and records we have not to enable us to understand, and to justify their applications. But it is not so easy a matter to show, or to persuade the world to believe, that a chain of prophecies reaching through several thousand years, delivered at different times, yet manifestly subservient to one and the same administration of providence from beginning to end, is the effect of art and contrivance and religious fraud. In examining the several prophecies

16 Were all intended to keep alive a sense of religion.

17 The prophecies to be considered in connection.

(A) This they certainly could not know from the promises expressed in the very general terms in which they are recorded in the book of Genesis. It is, however, not improbable that those promises, as they immediately received them, were conceived in terms more precise and particular; and, at all events, Dr Warburton has proved to the full conviction of every man who is not a determined unbeliever, that Abraham was commanded to sacrifice his son Isaac, not only as a trial of his obedience, but also that God might give him what he earnestly desired, a scenical representation of the means by which mankind were to be redeemed from death. The learned writer thinks, and his reasoning compels us to think with him, that to this transaction our Saviour alludes when he says, "Your father Abraham rejoiced to see my day, and he saw it and was glad."

Prophecy. cies recorded in the Old Testament, we are not to suppose that each of them *expressly* pointed out and *clearly* characterized Jesus Christ. Had they done so, instead of being a support to religion in general, the purpose for which they were originally intended, they would have had a very different effect, by making those to whom they were given repine at being placed under dispensations so very inferior to that of the gospel. We are therefore to inquire only whether all the notices, which, in general and often metaphorical terms, God gave to the fathers, of his intended salvation, are perfectly answered by the coming of Christ; and we shall find that nothing has been promised with respect to that subject which has not been performed in the amplest manner. If we examine the prophecies in this manner, we shall find that there is not one of them, which the Apostles have applied to the Messiah, that is not applicable in a rational and important sense to something in the birth, life, preaching, death, resurrection, and ascension of Jesus of Nazareth; that as applied to him they are all consistent with each other; and that though some few of them may be applied without absurdity to persons and events under the Jewish dispensation, Christ is the only person that ever existed in whom they all meet as in a centre. In the limits prescribed us, it is impossible that we should enter upon a particular proof of this position. It has been proved by numberless writers, and, with respect to the most important prophecies, by none with greater success than bishop Sherlock in his *Use and Intent of Prophecy in the several ages of the world*; a work which we recommend to our readers as one of the most valuable on the subject in our own or any other language.

18
Objection
from the
obscurity
of prophe-
cy,

But admitting that it would have been improper, for the reasons already hinted at, to have given a clear and precise description of Christ, and the Christian dispensation, to men who were ordained to live under dispensations less perfect, how, it may be asked, comes it to pass that many of the prophecies applied by the writers of the gospel to our Saviour and his actions are still dark and obscure, and so far from belonging evidently to him and to him only, that it requires much learning and sagacity to show even now the connection between some prophecies and the events?

19
Answered.

In answer to these questions, the learned prelate just referred to observes, "That the obscurity of prophecy does not arise from hence, that it is a relation or description of something *future*; for it is as easy to speak of things future plainly, and intelligibly, as it is of things past or present. It is not, therefore, of the nature of prophecy to be obscure; for it may easily be made, when he who gives it thinks fit, as plain as history. On the other side, a figurative and dark description of a future event will be figurative and dark still when the event happens; and consequently will have all the obscurity of a figurative and dark description as well after as before the event. The prophet Isaiah describes the peace of Christ's kingdom in the following manner: 'The wolf shall dwell with the lamb, and the leopard shall lie down with the kid, and the calf and the young lion, and the fatling, together, and a little child shall lead them.' Nobody, some modern Jews excepted, ever understood this literally; nor can it now be *literally* applied to the state of the gospel. It was and is capable of different interpretations: it may mean tem-

poral peace, or that internal and spiritual peace—that tranquillity of mind, which sets a man at peace with God, himself, and the world. But whatever the true meaning is, this prophecy does no more obtrude one determinate sense upon the mind since the coming of Christ than it did before. But then we say, the state of the gospel was very properly prefigured in this description, and is as properly prefigured in a hundred more of the like kind; and since they all agree in a fair application to the state of the gospel, we strongly conclude, that this state was the thing foretold under such expressions. So that the argument from prophecy for the truth of Christianity does not rest on this, that the event has necessarily limited and ascertained the particular sense and meaning of every prophecy; but in this, that every prophecy has in a proper sense been completed by the coming of Christ. It is absurd, therefore, to expect clear and evident conviction from every single prophecy applied to Christ; the evidence must arise from a view and comparison of all together." It is doubtless a great mistake to suppose that prophecy was intended solely or chiefly for their sakes in whose time the events predicted are to happen. What great occasion is there to lay in so long beforehand the evidence of prophecy to convince men of things that are to happen in their own times; the truth of which they may, if they please, learn from their own senses? Yet some people are apt to talk as if they thought the truth of the events predicted depended very much on the evidence of prophecy: they speak, for instance, as if they imagined the certainty and reality of our Saviour's resurrection were much concerned in the clearness of the prophecies relating to that great and wonderful event, and seem to think that they are confusing the truth of his resurrection when they are pointing out the absurdity of the prophecies relating to it. But can any thing be more absurd? For what ground or pretence is there to inquire whether the prophecies foretelling that the Messiah should die and rise again do truly belong to Christ, unless we are first satisfied that Christ died and rose again?

The part which unbelievers ought to take in this question, if they would make any use of prophecy, should be, to show from the prophets that Christ was necessarily to rise from the dead; and then to prove that in fact Jesus never did rise. Here would be a plain consequence. But if they like not this method, they ought to let the prophecies alone; for if Christ did not rise, there is no harm done though the prophets have not foretold it. And if they allow the resurrection of Christ, what do they gain by discrediting the prophets? The event will be what it is, let the prophecies be what they will.

These considerations show how far the gospel is *necessarily* concerned in prophetic evidence, and how clear the prophecies should be. Christ claims to be the person foretold in the law and the prophets; and as truth must ever be consistent with itself, this claim must be true as well as all others. This is the part then to be tried on the evidence of prophecy: Is Christ that person described and foretold under the Old Testament or not? Whether all the prophecies relating to him be plain or not plain, it matters little; the single question is, Are there enough plain to show us that Christ is the person foretold under the Old Testament? If there be,

Prophecy.

Prophecy. we are at an end of our inquiry, and want no farther help from prophecy; especially since we have seen the day dawn and enjoyed the marvellous light of the gospel of God.

20
Objections But so unreasonable are unbelievers, that whilst some of them object to the obscurity of the prophecies, others have rejected them altogether on account of their clearness, pretending that they are histories and not predictions. The prophecies against which this objection has been chiefly urged are those of Daniel, which were first called in question by the famous Porphyry. He affirmed that they were not composed by Daniel, whose name they bear, but by some author who lived in Judea about the time of Antiochus Epiphanes; because all to that time contained true history, but that all the facts beyond that were manifestly false.

21
Answered. This method of opposing the prophecies, as a father of the church rightly observes, is the strongest testimony of their truth: for they are so exactly fulfilled, that to infidels the prophet seemed not to have foretold things future, but to have related things past. To an infidel of this age, if he has the same ability and knowledge of history that Porphyry had, all the subsequent prophecies of Daniel, except those which are still fulfilling, would appear to be history and not prophecy: for it entirely overthrows the notion of their being written in the days of *Antiochus Epiphanes*, or of the *Maccabees*, and establishes the credit of Daniel as a prophet beyond contradiction, that there are several of those prophecies which have been fulfilled since that period as well as before; nay, that there are prophecies of Daniel which are fulfilling at this very time in the world.

22
From what Our limits will not permit us to enter into the objections which have been made to this prophet by the author of *The Literal Scheme of Prophecy Considered*; nor is there occasion that we should enter into them. They have been all examined and completely answered by Bishop Chandler in his *Vindication of his Defence of Christianity*, by Mr Samuel Chandler in his *Vindication of the Antiquity and Authority of Daniel's Prophecies*, and by Bishop Newton in his excellent *Dissertations on the Prophecies*. To these authors we refer the reader; and shall conclude the present article with a view of some prophecies given in very remote ages, which are in this age receiving their accomplishment.

23
And from Of these the first is that of Noah concerning the servitude of the posterity of Canaan. In the greater part of original manuscripts, and in our version of the holy scriptures, this prophecy is thus expressed: "Cursed be Canaan; a servant of servants shall he be unto his brethren;" but in the Arabic version, and in some copies of the Septuagint, it is, "Cursed be *Ham* the father of Canaan; a servant of servants shall he be to his brethren." Whether the curse was really pronounced upon Ham, which we think most probable, or only upon his son Canaan, we shall find the prediction remarkably fulfilled, not barely ages after the book of Genesis was very generally known, but also at this very day. It is needless to inform any man who has but looked into the Old Testament, that when the ancient patriarchs pronounced either a curse or a blessing upon any of their sons, they meant to declare the future fortunes, not of that son individually, but of his descendants as a tribe or a nation. Let us keep this in mind,

Prophecy. and proceed to compare with Noah's prophecy *first* the fortunes of the descendants of Canaan, the fourth son of Ham, and then the fortunes of the posterity of Ham by his other sons.

With the fate of the Canaanites every reader is acquainted. They were conquered by Joshua several centuries after the delivery of this prophecy; and such of them as were not exterminated were by him and Solomon reduced to a state of the lowest servitude to the Israelites, the posterity of Shem the brother of Ham. The Greeks and Romans, too, who were the descendants of Japheth, not only subdued Syria and Palestine, but also pursued and conquered such of the Canaanites as were anywhere remaining, as for instance the Tyrians and Carthaginians, of whom the former were ruined by Alexander and the Grecians, and the latter by Scipio and the Romans. Nor did the effects of the curse stop there. The miserable remainder of that devoted people have been ever since slaves to a foreign yoke; first to the Saracens who are descended from Shem, and afterwards to the Turks who are descended from Japheth; and under the Turkish dominion they groan at this day.

If we take the prophecy as it stands in the Arabic version, its accomplishment is still more remarkable. The whole continent of Africa was peopled principally by the posterity of Ham. And for how many ages have the better parts of that country lain under the dominion first of the Romans, then of the Saracens, and now of the Turks? In what wickedness, ignorance, barbarity, slavery, and misery, live most of its inhabitants? and of the poor negroes how many thousands are every year sold and bought like beasts in the market, and conveyed from one quarter of the world to do the work of beasts in another; to the full accomplishment indeed of the prophecy, but to the lasting disgrace of those who are from the love of gain the instruments of fulfilling it. Nothing can be more complete than the execution of the sentence as well upon Ham as upon Canaan; and the hardiest infidel will not dare to say that it was pronounced after the event.

The next prophecy which we shall notice is that of Abraham concerning the multitude of his descendants; which every one knows is still fulfilled in the Jews even in their dispersed state, and therefore cannot have been given after the event of which it speaks.

Of the same kind are the several prophecies concerning Ishmael; of which some have been fulfilled, and others are at present fulfilling in the most astonishing manner. Of this son of Abraham it was foretold, that "he should be a wild man; that his hand should be against every man, and every man's hand against him; that he should dwell in the presence of all his brethren; that he should be multiplied exceedingly, beget twelve princes, and become a great nation." The sacred historian who records these prophecies adds, that "God was with the lad, and he grew, and dwelt in the wilderness, and became an archer."

To show how fully and literally all these prophecies have been accomplished, would require more room than we have to bestow; and to the reader of history the labour would be superfluous. We shall therefore only request the unbeliever to attend to the history of the Arabs, the undoubted descendants of Ishmael; and to say how it comes to pass, that though they have been robbers by land and pirates by sea for time immemorial,

Prophecy. rial, though their hands have been against every man, and every man's hand against them, they always have dwelt, and at this day dwell, in the presence of their brethren, a free and independent people. It cannot be pretended that no attempt has ever been made to conquer them; for the greatest conquerors in the world have all in their turns attempted it: but though some of them made great progress, not one was ever crowned with success. It cannot be pretended that the inaccessibility of their country has been their protection; for their country has been often penetrated, though it never was entirely subdued. When in all human probability they have been on the brink of ruin, they were signally and providentially delivered. Alexander was preparing an expedition against them, when he was cut off in the flower of his age. Pompey was in the career of his conquests, when urgent affairs called him elsewhere. Ælius Gallus had penetrated far into their country, when a fatal disease destroyed great numbers of his men, and obliged him to return. Trajan besieged their capital city, but was defeated by thunder and lightning and whirlwinds. Severus besieged the same city twice, and was twice repelled from before it. The Turks, though they were able to wrest from them their foreign conquests, have been so little able to subdue the Arabs themselves, or even to restrain their depredations, that they are obliged to pay them a sort of annual tribute for the safe passage of the pilgrims who go to Mecca to pay their devotions. On these facts we shall not exclaim. He who is not struck upon comparing the simple history of this singular people with the prophecies so long ago delivered of them and their great ancestor, whose love of liberty is compared to that of the wild ass, would rise wholly unmoved from our exclamations.

²⁴
The dispersion of
the Jews
plainly
foretold,

A fourth prophecy of this kind, which cannot be alleged to have been uttered after the event, is the denunciation of Moses against the children of Israel in case of their disobedience; which is so literally fulfilled, that even at this moment it appears rather a history of the present state of the Jews, than a remote prediction of their apostacy and punishment. "And the Lord shall scatter thee among all people from the one end of the earth even unto the other. And among these nations shalt thou find no ease, neither shall the sole of thy foot have rest; but the Lord shall give thee there a trembling heart, and failing of eyes, and sorrow of mind. And thy life shall hang in doubt before thee; and thou shalt fear day and night, and shalt have none assurance of thy life." (Deut. xxviii. 64, 65, 66.) "And thou shalt become an astonishment, a proverb, and a bye-word, among all nations, whither the Lord shall lead you." (Deut. xxviii. 37.)

Similar to this denunciation, but attended with some circumstances still more wonderful, is the following prediction of the prophet Hosea: "The children of Israel shall abide many days without a king, and without a prince, and without a sacrifice, and without an image, and without an ephod, and without teraphim. Afterwards shall the children of Israel return, and seek the

VOL. XV.

Lord their God, and David their king; and shall fear the Lord and his goodness in the latter days (B)" In this passage we find the state of the Jews for the last 1700 years clearly and distinctly described with all its circumstances. From the time that they rejected their Messiah all things began to work towards the destruction of their politics both civil and religious; and within a few years from his death, their city, temple, and government, were utterly ruined; and they themselves, not carried into a gentle captivity, to enjoy their laws, and live under governors of their own as they did in Babylon, but they were sold like beasts in a market, and became slaves in the strictest sense; and from that day to this have had neither prince nor chief among them. Nor will any one of them ever be able, after all their pretences, to prove his descent from Aaron, or to say with certainty whether he is of the tribe of Judah or of the tribe of Levi, till he shall discover that unknown country where never mankind dwelt, and where the apocryphal Esdras has placed their brethren of the ten tribes. This being the case, it is impossible they can have either an altar, or a sacrifice, or a priesthood, according to the institution of Moses, but are evidently an outcast people living under laws which cannot be fulfilled.

The cause of this deplorable condition is likewise assigned with the same perspicuity: They are scattered over the face of the earth, because they do not acknowledge Christ for the Messiah; because they do not submit to their own king, the true David. In the prophetic writings the name of David is frequently given to the Messiah, who was to descend from that prince. Thus Ezekiel, speaking of the kingdom of Christ, says, "I will set up one Shepherd over them, and he shall feed them, even my servant David; he shall feed them, and he shall be their shepherd." And Jeremiah says, "They shall serve the Lord their God, and David their king, whom I shall raise up unto them."

That in these places, as well as in the passage under consideration, the Messiah is meant, is undeniable; for David the son of Jesse was dead long before any of the three prophets was born, and by none of them it is said, "afterwards David their king shall come again;" but "afterwards the children of Israel shall return to David their king," they shall recover from their blind infatuation, and seek him whom they have not yet known. By their not receiving Jesus for the Christ, they have forfeited all claim to the divine favour, and are, of consequence, "without a king, and without a chief, and without a sacrifice, and without an altar, and without a priesthood."

The time, however, will come, when they shall return and seek "the Lord their God and David their king;" when they shall tremble before him whom their fathers crucified, and honour the son even as they honour the father. That this part of the prophecy will in time be as completely fulfilled as the other has been, may be confidently expected from the wonderful preservation of the Jews for so many ages. Scattered as they

4 G

(B) Such is our translation of this remarkable prophecy; but the Greek version of the Seventy has it, perhaps more properly, thus: "The children of Israel shall abide many days without a king, and without a chief, and without sacrifice, and without an altar, and without a priesthood, and without prophecies. Afterwards," &c.

they are over the whole earth, and hated as they are by all nations, it might naturally be thought, that in process of time they would have coalesced with their conquerors, and have been ultimately absorbed and annihilated by the union, so that not a trace of them should now have remained; yet the fact is, that, dispersed as they have ever since been over the whole face of the globe, they have never, in a single instance in any country, lost their religious or national distinctions; and they are now generally supposed to be as numerous as they were under the reigns of David and Solomon. This is contrary to all history, and all experience of the course of human affairs in similar cases; it has been boldly and justly styled a standing miracle. Within 1000 or 1200 years back, a great variety of extraordinary and important revolutions have taken place among the nations of Europe. In the southern part of Britain the Britons were conquered by the Saxons, the Saxons by the Danes, and the Danes and Saxons by the Normans; but in a few centuries these opposite and hostile nations were consolidated into one indistinguishable mass. Italy, about the same time that Britain was subdued by the Saxons, was conquered by the Goths and Vandals: and it is not easy to conceive a more striking contrast than that which subsisted between the polished inhabitants of that delightful country and their savage invaders; and yet how soon did all distinction cease between them! In France, the Roman colonies gradually assimilated with the ancient Gauls; and in Spain, though the Moors continued for several ages, and till their final expulsion, a distinct people, yet after they were once reduced to a state of subjection, their numbers very sensibly diminished; and such of them as were suffered to remain after their last overthrow have been long since so blended with the Spaniards that they cannot now be distinguished. But with regard to the Jews, the wonder is, that though they do not in any country where they are settled bear any proportion to the natural inhabitants, though they are universally reduced to a state of the lowest subjection, and even exposed to hatred, contempt, and persecution; yet in no instance does there seem to be the least appearance or probability of their numbers being diminished, in no instance do they discover any decay of attachment to their religious principles. Whence then comes it that this people alone, who, having no form of government or a republic anywhere subsisting, are without the means by which other people are kept united and distinct, should still be preserved among so many different nations? How comes it, when they have been thus scattered into so many distant corners, like dust which cannot be perceived, that they should still so long survive the dissolution of their own state, as well as that of so many others? To these questions the answer is obvious: They are preserved, that, as a nation, "they may return and seek the Lord their God and David their king, and fear the Lord and his goodness in the latter days."

We might here subjoin many prophecies both from the Old and the New Testament, and especially from the writings of St Paul and St John, which so clearly describe the various fortunes of the Christian church, her progress to that state of general corruption under which she was sunk three centuries ago, and her gradual restoration to her primitive purity, that they cannot be supposed to proceed from the cunning craftiness

of men, or to have been written after the events of which they speak. To do justice to these, however, would require a volume, and many excellent volumes have been written upon them. The reader who wishes for satisfaction on so interesting a subject will do well to consult the writings of Mr Mede and Sir Isaac Newton, together with Bishop Newton's Dissertations, and the Sermons of Hurd, Halifax, and Bagot, preached at Warburton's lecture. We shall only observe, that one of the ablest reasoners that Great Britain ever produced, after having paid the closest attention to the predictions of the New Testament, hath been bold enough to put the truth of revealed religion itself upon the reality of that prophetic spirit which foretold the desolation of Christ's church and kingdom by antichrist. "If (says he), IN THE DAYS OF ST. PAUL AND ST. JOHN, there was any footstep of such a sort of power as this in the world; or if there HAD BEEN any such power in the world; or if there WAS THEN any appearance or probability that could make it enter into the heart of man to imagine that there EVER COULD BE any such kind of power in the world, much less in the temple or church of God; and if there be not NOW such a power actually and conspicuously exercised in the world; and if any picture of this power, DRAWN AFTER THE EVENT, can now describe it more plainly and exactly than it was originally described in the words of the prophecy—then may it, with some degree of plausibility, be suggested, that the prophecies are nothing more than enthusiastic imaginations."

Upon the whole, we conclude with Bishop Sherlock, that the various prophecies recorded in the Holy Scriptures were given, not to enable man to foresee with clearness future events, but to support the several dispensations of religion under which they were respectively promulgated. The principal prophecies recorded in the Old Testament led mankind to hope for a complete deliverance from the curse of the fall; and therefore tended to fill their minds with gratitude, and to enforce a cheerful obedience to that God who in the midst of judgment remembereth mercy. The prophecies, whether in the Old or New Testament, that portray the present state of the Jews, and the various fortunes of the Christian church, as they are daily fulfilling in the presence of all men, are the strongest possible proof of the divinity of our holy religion, and supply to us in the latter days the place of miracles, by which it was at first established.

PROPHET, in general, a person who foretells future events; but is particularly applied to such inspired persons among the Jews as were commissioned by God to declare his will and purposes to that people. Among the canonical books of the Old Testament we have the writings of 16 prophets, four of whom are denominated the *greater prophets*, viz. Isaiah, Jeremiah, Ezekiel, and Daniel; so called from the length or extent of their writings, which exceed those of the others, viz. Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habakkuk, Zephaniah, Haggai, Zechariah, and Malachi, who are called the *lesser prophets*, from the shortness of their writings. The Jews do not place Daniel among the prophets, because, they say, he lived the life of a courtier rather than that of a prophet. An account of the several writings of the prophets may be seen each under its particular head. See the article ISAAH, &c.

Sans

Prophet
||
Proportion

Sons of the PROPHETS, in scripture history, an appellation given to young men who were educated in the schools or colleges under a proper master, who was commonly, if not always, an inspired prophet, in the knowledge of religion and in sacred music, and thus were qualified to be public preachers; which seems to have been part of the business of the prophets on the Sabbath-days and festivals. It is probable that God generally chose the prophets, whom he inspired, out of these schools. See PROPHECY.

PROPTIATION, in theology, a sacrifice offered to God to assuage his wrath and render him propitious. Among the Jews, there were both ordinary and public sacrifices, as holocausts, &c. offered by way of thanksgiving; and extraordinary ones, offered by particular persons guilty of any crime, by way of propitiation. The Romish church believe the mass to be a sacrifice of propitiation for the living and the dead. The reformed churches allow of no propitiation but that one offered by Jesus Christ on the cross. See SACRIFICE.

PROPTIATORY, any thing rendering God propitious; as we say *propitiatory* sacrifices, in contradistinction to sacrifices which were *eucharistical*. Among the Jews the propitiatory was the cover or lid of the ark of the covenant; which was lined both within and without with plates of gold, inasmuch that there was no wood to be seen. This propitiatory was a type or figure of Christ, whom St Paul calls the propitiatory ordained from all ages. See ARK of the Covenant.

PROPOLIS, the name of a certain substance more tenacious than wax, with which the bees stop up all the holes or cracks in the sides of their hives. See BEE, n° 13.

PROPONTIS, or SEA OF MARMORA, a part of the Mediterranean, dividing Europe from Asia; it has the Hellespont or canal of the Dardanelles to the south-west, whereby it communicates with the Archipelago, and the ancient Bosphorus of Thrace, or Strait of Constantinople, to the north-east, communicating with the Black or Euxine Sea. It has two castles: that on the Asia side is on a cape, where formerly stood a temple of Jupiter. The castle of Europe is on an opposite cape, and had anciently a temple of Serapis. It is 120 miles long, and in some places upwards of 40 miles broad.

PROPORTION, the identity or similitude of two ratios. Hence quantities that have the same ratio between them are said to be proportional; *e. gr.* if A be to B as C to D, or 8 be to 4 as 30 to 15; A, B, C, D, and 8, 4, 30, and 15, are said to be in proportion, or are simply called proportionals. Proportion is frequently confounded with ratio; yet have the two in reality very different ideas, which ought by all means to be distinguished. Ratio is properly that relation or habitude of two things, which determines the quantity of one from the quantity of another, without the intervention of any third: thus we say the ratio of 5 and 10 is 2, the ratio of 12 and 24 is 2. Proportion is the sameness or likeness of two such relations: thus the relations between 5 and 10 and 12 and 24 being the same, or equal, the four terms are said to be in proportion. Hence ratio exists between two numbers, but proportion requires at least three. Proportion, in fine, is the habitude or relation of two ratios when compared toge-

ther; as ratio is of two quantities. See ALGEBRA, ARITHMETIC, and GEOMETRY.

Arithmetical and Geometrical PROPORTION. See PROGRESSION.

Harmonical or Musical PROPORTION, is a kind of numeral proportion formed thus: of three numbers, if the first be to the third as the difference of the first and second to the difference of the second and third; the three numbers are in harmonical proportion.

Thus 2, 3, 6, are harmonical, because $2 : 6 :: 1 : 3$. So also four numbers are harmonical, when the first is to the fourth as the difference of the first and second to the difference of the third and fourth.

Thus 24, 16, 12, 9, are harmonical, because $24 : 9 :: 8 : 3$. By continuing the proportional terms in the first case, there arises an harmonical progression or series.

1. If three or four numbers in harmonical proportion be multiplied or divided by the same number; the products or quotients will also be in harmonical proportion: thus, if 6, 8, 12, which are harmonical, be divided by 2, the quotients 3, 4, 6, are also harmonical; and reciprocally their products by 2, viz. 6, 8, 12.

2. To find an harmonical mean between two numbers given; divide double the product of the two numbers by their sum, the quotient is the mean required; thus suppose 3 and 6 the extremes, the product of these is 18, which doubled gives 36; this divided by 9 (the sum of 3 and 6) gives the quotient 4. Whence 3, 4, 6, are harmonical.

3. To find a third harmonical proportional to two numbers given.

Call one of them the first term, and the other the second: multiply them together, and divide the product by the number remaining after the second is subtracted from double the first; the quotient is a third harmonical proportional: thus, suppose the given terms 3, 4, their product 12 divided by 2 (the remainder after 4 is taken from 6, the double of the first), the quotient is 6, the harmonical third sought.

4. To find a fourth harmonical proportion to three terms given: multiply the first into the third, and divide the product by the number remaining after the middle or second is subtracted from double the first; the quotient is a third harmonical proportion; thus supposing the numbers 9, 12, 16, a fourth will be found by the rule to be 24.

5. If there be four numbers disposed in order, whereof one extreme and the two middle terms are in arithmetical proportion; and the same middle terms with the other extreme are in harmonical proportion, the four are in geometrical proportion; as here $2 : 3 :: 4 : 6$, which are geometrical; whereof 2, 3, 4, are arithmetical, and 3, 4, 6, harmonical.

6. If betwixt any two numbers you put an arithmetical mean, and also an harmonical one, the four will be in geometrical proportion: thus betwixt 2 and 6 an arithmetical mean is 4, and an harmonical one 3; and the four $2 : 3 :: 4 : 6$, are geometrical.

We have this notable difference between the three kinds of proportion, arithmetical, harmonical, and geometrical; that from any given number we can raise a continued arithmetical series increasing in *infinitum*, but

proportion not decreasing: the harmonical is decreasable in *infinitum*, but not increasable; the geometrical is both.

PROPORTION, or *Rule of Three*. See ARITHMETIC, n° 13, 14, 15.

Reciprocal PROPORTION. See RECIPROCAL.

PROPORTION is also used for the relation between unequal things of the same kind, whereby their several parts correspond to each other with an equal augmentation or diminution.

Thus, in reducing a figure into little, or in enlarging it, care is taken to observe an equal diminution or enlargement, through all its parts; so that if one line, *e. gr.* be contracted by one-third of its length, all the rest shall be contracted in the same proportion.

PROPORTION, in architecture, denotes the just magnitude of the members of each part of a building, and the relation of the several parts to the whole; *e. gr.* of the dimensions of a column, &c. with regard to the ordonnance of a whole building.

One of the greatest differences among architects, M. Perrault observes, is in the proportions of the heights of entablatures with respect to the thickness of the columns, to which they are always to be accommodated.

In effect, there is scarce any work, either of the ancients or moderns, wherein this proportion is not different; some entablatures are even near twice as high as others:—yet it is certain this proportion ought of all others to be most regulated; none being of greater importance, as there is none wherein a defect is sooner spied, nor any wherein it is more shocking.

Compass of PROPORTION, a name by which the French, and after them some English, authors call the **SECTOR**.

PROPORTIONAL, relating to proportion. Thus we say, proportional compasses, parts, scales, spirals, &c.

PROPORTIONALS, in geometry, are quantities, either linear or numeral, which bear the same ratio or relation to each other.

PROPOSITION, in logic, part of an argument wherein some quality, either negative or positive, is attributed to a subject.

PROPOSITION, in mathematics, is either some truth advanced and shown to be such by demonstration, or some operation proposed and its solution shown. If the proposition be deduced from several theoretical definitions compared together, it is called a *theorem*; if from a praxis, or series of operations, it is called a *problem*. See the articles **THEOREM** and **PROBLEM**.

PROPOSITION, in oratory. See **ORATORY**, n° 28. 124.

PROPOSITION, in poetry, the first part of a poem, wherein the author proposes briefly, and in general, what he is to say in the body of his work. It should comprehend only the matter of the poem, that is, the action and persons that act. Horace prescribes modesty and simplicity in the proposition, and would not have the poet promise too much, nor raise in the reader too great ideas of what he is going to relate.

PROPREFECT, among the Romans, the prefect's lieutenant, or an officer whom the prefect of the pretorium commissioned to do part of his duty in his place.

PROPRETOR, a Roman magistrate, who, having discharged the office of pretor at home, was sent into a province to command there with his former pretorial authority. It was also an appellation, given to those who, without having been pretors at Rome, were sent extraordinarily into the provinces to administer justice with the authority of pretors.

PROPRIETOR, or **PROPRIETARY**, is he who possesses any thing as his own in the utmost degree. Such monks were called *proprietary* as had reserved goods and effects to themselves, notwithstanding their formal renunciation of all at the time of their profession. They are frequently mentioned in the *Monast. Anglic. &c.* and were to be very severely dealt with; to be excommunicated, deprived of burial, &c. *Monachi proprietarii excommunicentur ab abbatibus: et, si in morte proprietarius inventus fuerit, ecclesiastica careat sepultura, &c.* Addit. ad Matt. Par.

PRO RATA, in commerce, a term sometimes used by merchants for *in proportion*; as each person must reap the profit or sustain the loss, *pro rata* to his interest, that is, in proportion to his stock.

PROROGATION, the act of prolonging, adjourning, or putting off, to another time. The difference between a prorogation and an adjournment of parliament is, that by prorogation the session is ended, and such bills as passed in either house, or both houses, and had not the royal assent, must at the next assembly begin again.

PROSCRIPTION, a publication made in the name of the chief or leader of a party, whereby he promises a reward to any one who shall bring him the head of one of his enemies.

Sylla and Marius by turns proscribed each other's adherents.—Under the triumvirate a great part of the best and bravest of the Romans fell by proscription.

The term took its rise from the practice of writing down a list of the persons names, and posting it in public; from *pro* and *scribo* "I write."

PROSE, the natural language of mankind, loose and unconfined by poetical measures, rhymes, &c. In which sense it stands opposed to verse.

There is, however, a species of prose which is measured, such as that in which epitaphs and other inscriptions are generally written; and indeed every man who has formed for himself a style writes in uniform periods regularly recurring. It has been much disputed whether a poem can be written in prose. We enter not into that dispute, as we have said enough on the subject elsewhere. See **NOVEL**.

The word *prose* comes from the Latin *prosa*, which some will have derived from the Hebrew *poras*, which signifies *expendit*: others deduce it from the Latin *prosa*, of *prorsus*, "going forwards;" by way of opposition to *versa*, or "turning backwards," as is necessary in writing.

PROSECUTION, in the criminal law. The next step towards the punishment of offenders after **COMMITMENT**, is their prosecution, or the manner of their formal accusation. And this, in the English law, is either upon a previous finding of the fact by an inquest or grand jury; or without such previous finding.

The former way is either by **PRESENTMENT** or **INDICTMENT**. See these articles.

Propretor
||
Prosecution.

Prosecutor
Proslam-
banomene.

The remaining methods of prosecution are without any previous finding by a jury, to fix the authoritative stamp of verisimilitude upon the accusation. One of these, by the common law, was when a thief was taken *with the mainour*, that is, with the thing stolen upon him, *in manu*. For he might, when so detected, *flagrante delicto*, be brought into court, arraigned, and tried, without indictment: as by the Danish law he might be taken and hanged upon the spot without accusation or trial. But this proceeding was taken away by several statutes in the reign of Edward III. though in Scotland a similar process remains to this day. So that the only species of proceeding at the suit of the king, without a previous indictment or presentment by a grand jury, now seems to be that of INFORMATION; which see.

These are all the methods of prosecution at the suit of the king. There yet remains another, which is merely at the suit of the subject, and is called an APPEAL. See that article.

But of all the methods of prosecution, that by indictment is the most general. See INDICTMENT.

PROSECUTOR, in law, he that pursues a cause in another's name.

PROSELYTE, a new convert to some religion or religious sect.

PROSERPINACA, in botany: A genus of the trigynia order, belonging to the triandria class of plants; and in the natural method ranking under the 15th order, *Inundata*. The calyx is tripartite superior; there is no corolla; there is one trilocular seed.

PROSERPINE, in fabulous history, the daughter of Jupiter and Ceres, was carried off by Pluto as she was gathering flowers with her companions. Ceres, disconsolate for the loss of her daughter, after having long sought her, heard where she was, and intreated Jupiter to let her return from hell. This request Jupiter granted, on condition she had tasted nothing in Pluto's dominions. Ceres therefore went to fetch her; but when her daughter was preparing to return, Ascalaphus gave information that he had seen Proserpine eat some grains of a pomegranate she had gathered in Pluto's garden; on which she was sentenced to continue in Tartarus in quality of Pluto's spouse, and the queen of those gloomy regions: but to mitigate the grief of Ceres for her disappointment, Jupiter granted that her daughter should only spend six months together in hell with her husband, and the other six on earth with her mother.

Some mythologists imagine that the latter part of the fable alludes to the corn, which must remain all the winter hid in the earth, in order to sprout forth in the spring, and produce the harvest.

PROSEUCHE, in antiquity, properly signifies *prayer*; but it is taken for the places of prayer of the Jews, and was pretty near the same as their synagogues. But the synagogues were originally in the cities, and were covered places: whereas, for the most part, the proseuches were out of the cities, and on the banks of rivers; having no covering, except perhaps the shade of some trees or covered galleries. The word is Greek, *προσευχη* *prayer*.

PROSLAMBANOMENE, the name of a musical note in the Greek system.

As the two tetrachords of the Greeks were conjunc-

tive, or, in other words, as the highest note of the first served likewise for the lowest note of the second, it is plain that a complete octave could not be formed. To remedy this deficiency, therefore, one note beneath the lowest tetrachord was added, as an octave to the highest of the last tetrachord. Thus, if we suppose the first to have begun on B, the last must have ended upon A, to which one note subjoined immediately beneath the lowest B in the diatonic order must have formed an octave. This note was called *proslambanomene*. But it appears from authors who have scrutinized antiquity with some diligence, and perhaps with as much success as the data upon which they proceeded could produce, that the names of the notes in the Greek system, which originally signified their natural station in the scale of ascending or descending sounds, were afterwards applied to their positions in the lyre. *Higher* or *lower*, then, according to this application, did not signify their degrees of acuteness or gravity, but their higher or lower situation upon this instrument.

PROSODY, that part of grammar which treats of the quantities and accents of syllables, and the manner of making verses.

The English prosody turns chiefly on two things, numbers and rhyme. See POETRY, n° 66—76. and Part III.

PROSOPIS, in botany: A genus of the monogynia order, belonging to the decandria class of plants. The calyx is hemispherical and quadridentate; the stigma is simple; the legumen inflated and monospermous.

PROSOPOPEIA, a figure in oratory, whereby we raise qualities of things inanimate into persons. See ORATORY, p. 539 and 452.

PROSTATÆ, in anatomy, a gland, generally supposed to be two separate bodies, though in reality but one, situated just before the neck of the bladder, and surrounding the beginning of the urethra. See ANATOMY, p. 738. col. 2.

PROSTYLE, in architecture, a range of columns in the front of a temple.

PROTAGORAS, a famous Greek philosopher, was born at Abdera. In his youth, his poverty obliged him to submit to the servile office of frequently carrying logs of wood from the neighbouring fields to Abdera. It happened, that as he was one day going on briskly towards the city under one of these loads, he was met by Democritus, who was particularly struck with the neatness and regularity of the bundle. Desiring him to stop and rest himself, Democritus examined more closely the structure of the load, and found that it was put together with mathematical exactness; upon which he asked the youth whether he himself had made it up. Protagoras assured him that he had; and immediately taking it to pieces, with great ease replaced every log in the same exact order as before. Democritus expressed much admiration of his ingenuity: and said to him, "Young man, follow me, and your talents shall be employed upon greater and better things." The youth consented, and Democritus took him home, maintained him at his own expence, and taught him philosophy, which qualified him for the office of legislator of the Thurians. He was more subtle than solid in his reasonings; however, he taught at Athens with great reputation, but was at length

length banished from thence for the impiety of his doctrines. He then travelled, and visited the islands in the Mediterranean, where it is said that he was the first philosopher who taught for money. He died in a voyage to Sicily, in a very advanced age. He commonly reasoned by dilemmas, and left the mind in suspense with respect to all the questions, he proposed. His moral principles were adopted by Hobbes. (See MORAL PHILOSOPHY). Plato wrote a dialogue against him. He flourished 400 years B. C.

PROTASIS, in the ancient drama, the first part of a comic or tragic piece, wherein the several persons are shown, their characters intimated, and the subject of the piece proposed and entered upon.

It might reach as far as our two first acts; and where it ended the epitasis commenced. See the article EPITASIS.

PROTEA, the SILVER-TREE: A genus of the monogynia order, belonging to the tetrandria class of plants; and in the natural method ranking under the 47th order, *Stellata*. There is one quadrifid petal surrounding the germ; there is no proper calyx; the receptacle is paleaceous. There are 36 species, all natives of the Cape of Good Hope; of which the most remarkable are, 1. The conifera, with linear, spear-shaped, entire leaves, grows to the height of 10 or 12 feet, with a straight regular stem. The branches naturally form a large regular head. The leaves are long and narrow, of a shining silver colour; and as they remain the whole year, make a fine appearance in the greenhouse. 2. The argentea, commonly called *silver-tree*, has a strong upright stem covered with purplish bark, dividing into several branches which grow erect, garnished with broad, shining, silvery leaves, which make a fine appearance when intermixed with other exotics. Through the whole year it exhibits its glossy white or silvery leaves. It has at first a very uncommon and beautiful appearance, and sometimes in the course of 12 or 15 years reaches the height of 20 feet, which it never exceeds. In a rich soil it grows twice as quick, and is by far the largest of the protea kind. They are generally planted near some farms, and very seldom grow wild; Mr Sparman * thinks it was probably brought to the Cape of Good Hope from *Anamaqua*; for he had travelled over the whole north-east side of Hottentot's Holland, without finding it either in its wild state or planted. 3. The nitida, or wageboom, greatly resembles the second sort: the leaves are very silky and white, with erect purple branches.

All these plants, being tender exotics, require to be continually kept in the greenhouse during winter. The first may be propagated by cuttings, which should be cut off in April, just before the plants begin to shoot; the second and third sorts may be propagated by seeds.

PROTECTOR, a person who undertakes to shelter and defend the weak, helpless, and distressed.

Every Catholic nation, and every religious order, has a protector residing at the court of Rome, who is a cardinal, and is called the *cardinal protector*.

Protector is also sometimes used for a regent of a kingdom made choice of to govern it during the minority of a prince.

Cromwell assumed the title and quality of *lord protector of the commonwealth of England, &c.*

PROTESILAI TURRIS, the sepulchre of Protesilaus, with a temple, at which Alexander sacrificed, (Arian); situated at the south extremity of the Hellespont, next the Chersonesus Thracia. Protesilaus was the first Greek who landed on the coast of Troy, and the first Greek slain by the Trojans, (Homer, Ovid.) His wife Laodamia, to assuage her grief, begged the gods for a fight of his shade; and obtaining her request, she expired in his embraces, (Hyginus.) Protesilaus was also called *Phylacides*, from Phylace, a town of Thessaly.

PROTEST, in law, is a call of witness, or an open affirmation that a person does, either not at all, or but conditionally, yield his consent to any act, or to the proceeding of any judge in a court in which his jurisdiction is doubtful or to answer upon his oath farther than he is bound by law.

Any of the lords in parliament have a right to protest their dissent to any bill passed by a majority: which protest is entered in form. This is said to be a very ancient privilege. The commons have no right to protest. See PARLIAMENT.

PROTEST, in commerce, a summons written by a notary-public to a merchant, banker, or the like, to accept or discharge a bill of exchange drawn on him, after his having refused either to accept or pay it. See *BILL of Exchange*.

PROTESTANT, a name first given in Germany to those who adhered to the doctrine of Luther; because in 1529 they protested against a decree of the Emperor Charles V. and the diet of Spire; declaring that they appealed to a general council. The same name has also been given to those of the sentiments of Calvin; and is now become a common denomination for all those of the reformed churches.

PROTEUS, in heathen mythology. See EGYPT, n° 6.

PROTHONOTARY, a term which properly signifies *first notary*, and which was anciently the title of the principal notaries of the emperors of Constantinople.

Prothonotary, in England, is used for an officer in the court of king's bench and common-pleas; the former of which courts has one, and the latter three. The prothonotary of the king's bench records all civil actions sued in that court, as the clerk of the crown-office does all criminal causes. The prothonotaries of the common pleas enter and enrol all declarations, pleadings, affizes, judgments, and actions: they also make out all judicial writs, except writs of *habeas corpus*, and *distingas jurator*, for which there is a particular office, called the *habeas corpora office*: they likewise enter recognizances acknowledged, and all common recoveries; make exemplifications of records, &c.

In the court of Rome there is a college of 12 prelates, called *apostolical prothonotaries*, empowered to receive the last wills of cardinals, to make all informations and proceedings necessary for the canonization of saints, and all such acts as are of great consequence to the Papacy: for which purpose they have the right of admission into all consistories, whether public or half public. They also attend on the pope, whenever he performs any extraordinary ceremony out of Rome.

PROTO, a Greek term, frequently used in composition of priority: thus, proto-collum, in the ancient jurisprudence,

Protesilai
||
Proto.

* Voyage to the Cape of Good Hope, Vol. I. p. 33.

Protophages jurisprudence, signifies the first leaf of a book; **protomartyr**, the first martyr; **proto-plast**, the first man formed, &c.

PROTOGENES, a celebrated ancient painter, was born at Caunas, a city of Caria, subject to the Rhodians, and flourished 300 years before the birth of our Saviour. He was at first obliged to paint ships for his livelihood; but afterwards acquired the highest reputation for history-painting; though Appelles blamed him for finishing his pieces too highly, and not knowing when to have done. The finest of his pictures was that of Jafus, which is mentioned by several ancient authors, though none of them give any description of it. He worked seven years on this picture; during which time he lived entirely upon lupines and water, being of opinion that this light and simple nourishment left him greater freedom of fancy. Apelles, on seeing this picture, was struck with such admiration, that he was unable to speak, or to find words sufficient to express his idea of its beauty. It was this picture that saved the city of Rhodes when besieged by Demetrius king of Macedon; for being able to attack it only on that side where Protophages worked, which he intended to burn, he chose rather to abandon his design than to destroy so fine a piece. Pliny says, that Apelles asking him what price he had for his pictures, and Protophages naming an inconsiderable sum, Apelles, concerned at the injustice done to the beauty of his productions, gave him 50 talents, about 10,000*l.* for one picture only, declaring publicly that he would sell it for his own. This generosity made the Rhodians sensible of the merit of Protophages; and they were so eager to purchase the picture Apelles had bought, that they paid him a much greater price for it than he had given.

PROTOTYPE, is the original or model after which a thing was formed; but chiefly used for the patterns of things to be engraved, cast, &c.

PROTRACTOR, an instrument for laying down and measuring angles upon paper with accuracy and dispatch; and by which the use of the line of chords is superseded. This instrument is variously formed, as semicircular, rectangular, or circular; and constructed of different materials, as brass, ivory, &c. It is necessary in laying down those surveys or other plans where angles are concerned. For the semicircular protractor, and its use in laying down and measuring angles, see **GEOMETRY**, p. 676. prop. xx. &c.

The rectangular protractor is constructed in form of a right-angled parallelogram, which, when applied to a case of mathematical instruments, is substituted in place of the semicircular protractor and scale of equal parts. Fig. 1. is a representation of it: the manner of using it is exactly similar to that of the semicircular one.

The circular protractor, as its name implies, is a complete circle, and is superior by far to either of the former, both in point of accuracy and dispatch, especially when several angles are to be formed at the same point. The limb of this instrument is divided into 360 degrees, and each degree in some protractors is halved: it has a subdividing scale or vernier, by which an angle may be laid down or measured to a single minute. In the centre of the protractor is a fine mark, which, when an angle is to be protracted or measured,

is to be laid upon the angular point, and 0, or zero on the limb, upon the given line forming one side of the angle.

Fig. 2. represents a circular protractor whose limb is divided as above described, and the dividing scale on the index, which moves round the limb of the protractor on a conical centre, gives every minute of a degree. That part of the index beyond the limb has a steel point fixed at the end, in a direct line with the centre of the protractor, and whose use is to prick off the proposed angles.

Fig. 3. is another circular protractor, a little differently constructed from the former. The central point is formed by the intersection of two lines crossing each other at right angles, which are cut on a piece of glass. The limb is divided into degrees and half degrees, having an index with a vernier graduated to count to a single minute, and is furnished with a tooth and pinion, by means of which the index is moved round by turning a small nut. It has two pointers, one at each end of the index, furnished with springs for keeping them suspended while they are bringing to any angle; and being brought, applying a finger to the top of the pointer, and pressing it down, pricks off the angle. There is this advantage in having two pointers, that all the bearings round a circuit may be laid or pricked off, although the index traverses but one half of the protractor.

Another circular protractor, different from either of the former, is represented at fig. 4. The centre is also formed by the intersection of two lines at right angles to each other, which are cut on glass, that all parallax may thereby be avoided. The index is moved round by a tooth and pinion. The limb is divided into degrees and half degrees, and subdivided to every minute by the vernier. The pointer may be set at any convenient distance from the centre, as the socket which carries it moves upon the bar BC, and is fixed thereto by the nut D, at right angles to the bar BC, and moveable with it. There is another bar EF: On this bar different scales of equal parts are placed; so that by moving a square against the inner edge thereof, angles may be transferred to any distance within the limits, from the centre containing the same number of degrees marked out by the index.

It would indeed be superfluous to describe any more of these circular protractors, especially as the little alterations in them depend very much upon the fancy of the artist. Suffice it however to say, that we have seen others still differently constructed, one of which we shall briefly describe. The divisions upon the limb of this instrument are similar to those already described; but the index is a straight bar continued to some considerable distance each way beyond the limb of the instrument, and has a vernier to show minutes as usual; a mark upon one of the edges of the index always coincides with the centre of the instrument. Instead, therefore, of pricking down the angle as in the former, part of the line containing the angle may be drawn, which, although perhaps not so accurate as a point, is more conspicuous, and the line is easily completed upon removal of the protractor. The common dimensions of the circular part of these instruments is from six to ten inches diameter; and they are made of brass.

PROTUBERANCE,

Protuberance
↓
Providence

PROTUBERANCE, in anatomy, is any eminence, whether natural or preternatural, that projects or advances out beyond the rest.

PROVEDITOR, an officer in several parts of Italy, particularly at Venice, who has the direction of matters relating to policy.

PROVENCE, a province or government of France, bounded by Dauphine on the north, by Piedmont on the east, by the Mediterranean on the south, and by the river Rhone, which separates it from Languedoc, on the west: it is about 100 miles long, and near as many broad.

PROVEND, or **PROVENDER**, originally signified a kind of vessel containing the measure of corn daily given to a horse, or other beast of labour, for his subsistence; but is now generally used to signify the food for cattle, whatever it is.

PROVERB, according to Cambden, is a concise, witty, and wise speech, grounded upon experience, and for the most part containing some useful instruction.

Book of PROVERBS, a canonical book of the Old Testament, containing a part of the proverbs of Solomon the son of David king of Israel. The first 24 chapters are acknowledged to be the genuine work of that prince; the next five chapters are a collection of several of his proverbs made by order of king Hezekiah; and the two last seem to have been added, though belonging to different and unknown authors, Agur the son of Jakeh, and king Lemuel.

In this excellent book are contained rules for the conduct of all conditions of life; for kings, courtiers, masters, servants, fathers, mothers, Children, &c.

1
Definition.

PROVIDENCE, the superintendence and care which God exercises over creation.

2
Relief of a
providence
universal,

That there exists a divine providence which attends to the affairs of this world, and directs their course, has been a received opinion among the human race in every country and in every period of history. Every altar that is erected, every prayer and every sacrifice that is offered up, affords a proof of this belief. So fully have men been convinced of the sincerity of each other's faith upon this subject, that in one form, that of an appeal to the Divine Ruler of the world, by the solemnity of an oath, they have introduced it both into the most ordinary and the most important business of life.

3
Existence
of provi-
dence may
be proved
on scienti-
fic princi-
ples.

This universal conviction of men of all degrees of knowledge, from the most profound philosopher to the rudest barbarian, is probably to be traced to some primordial tradition, never totally effaced from any nation under heaven. The truth itself, however, is susceptible of the most complete proof from principles of science. If the world had a beginning, it may obviously have an end, and can be continued in existence only by the constant energy of that power by which it was at first created. He therefore who acknowledges a creation and denies a providence, involves himself in this palpable contradiction—"that a system, which of itself had not an original and momentary existence, may yet of itself have a perpetual existence; or that a being which cannot of itself exist for a second of time, may yet, of itself, exist for thousands of years?" Or should we be so complaisant, as for a moment to suppose, with certain theists, ancient and modern, that the *matter* of the universe is self-existent and eternal, and that the power of

God was exerted, not in creating substances, but in reducing the original matter from a state of chaos into that beautiful order in which we see it arranged; the constant energy of providence must still be admitted as necessary to preserve the forms and to continue the motions which were originally impressed upon the chaotic mass. From late experiments it appears extremely doubtful whether any two atoms of the most solid body be in actual contact; and that they are not *all* in contact is certain. (See *METAPHYSICS*, n° 176. and *OPTICS*, n° 46, 64, 66.) Yet it requires a very considerable degree of force to carry to a greater distance from one another the parts of a stone or of a bar of iron. By what power then are these parts kept contiguous? It cannot be by their own; because nothing can act where it is not present, and because our best philosophy has long taught us that the atoms of matter are essentially inactive. Again, it requires a very great degree of force to bring two bodies, however small, into *apparent* contact (see *OPTICS*, *ubi supra*); and therefore it follows that they must be kept asunder by some foreign power. Every attempt to solve these phenomena by the intervention of a subtle fluid is vain; for the question recurs, what keeps the parts of the fluid itself contiguous, and yet separated from each other?

The cohesion therefore of the parts of matter, and that which is called their repulsive power, demonstrate, through the whole system, the immediate energy of something which is not matter, and by which every body small and great is preserved in its proper form. It has been elsewhere shown (see *METAPHYSICS*, Part II. chap. 5. and *MOTION*, n° 19, 20), that the various motions which are regularly carried on through the universe, by which animals and vegetables grow and decay, and by which we have day and night, summer and winter, cannot be accounted for by any laws of mere mechanism, but necessarily imply the constant agency of something which is itself distinct from matter. But the forms of bodies are preserved, and their natural motions carried on, for purposes obviously planned by Wisdom. The power therefore which effects these things must be combined with intelligence: but power and intelligence preserving the order of the universe constitute all that is meant by a general providence; which is therefore as certainly administered as the sun daily rises and sets, or as bodies are kept solid by what is termed cohesion and repulsion.

Abstracted and metaphysical as this reasoning may appear, it is by no means peculiar to the philosophers of Europe. Its force has been felt from time immemorial by the Bramins of Hindostan, who, as Sir William Jones informs us*, "being unable to form a distinct idea of brute matter independent of mind, or to conceive that the work of supreme goodness was left a moment to itself, imagine that the Deity is ever present to his work, not in substance but in spirit and in energy." On this rational and sublime conception they have indeed built numberless absurd superpositions; but their holding the opinion itself, shows that they believe in the reality of providence upon philosophical principles: and what truth is there on which the mind of man has not ingrafted marks of its own weakness?

Few nations, however, except the ancient Greeks, have had philosophers equally subtle with the Bramins

Providence

* Asiatic
Researches
Vol. I.

Providence of India ; and therefore though all mankind have in general agreed in the belief of a superintending Providence, they have in different ages and countries admitted that truth upon different kinds of evidence, and formed very different notions concerning the mode in which the Divine superintendence is exerted.

5
Idea of
providence
in rude
ages.

While societies are still in a rude and unpolished state, while individuals possess little security and little leisure for the exertion of their rational powers, every important or singular appearance in nature becomes an object of wonder or of terror. In this state of ignorance, men see not the universe as it is, a great collection of connected parts, all contributing to form one grand and beautiful system. Every appearance seems to stand alone ; they know that it must have a cause, but what that cause is they are ignorant. The phenomena exhibited by nature are so complicated and so various, that it never occurs to them that it is possible for one Being to govern the whole. Hence arose the different systems of polytheism that have appeared in the world. Nature was divided into different regions, and a particular invisible power was assigned to each department : one conducted the flaming chariot of the sun, another wielded the terrible thunderbolt, and others were employed in diffusing plenty, and introducing the useful arts among men. Thus, although the various systems of polytheism in general acknowledged one Supreme Ruler, the father of gods and men, yet they at the same time peopled not only the regions above, the air and the heavens, but they also filled the ocean and the land, every grove, and every mountain, with active but invisible natures. Having arisen from the same causes, these systems of polytheism, which are so many hypotheses concerning Divine providence, are all extremely similar ; and we have a very favourable specimen of them in the elegant mythology of Greece and Rome, which gave to every region of nature a guardian genius, and taught men in the deep recesses of the forest, or in the windings of the majestic flood, to expect the presence of protecting and friendly powers. See POLYTHEISM.

6
The doctrine has
had opponents in
almost every
age.

Notwithstanding this universal reception, in some form or other, of the doctrine of a divine providence, it has in every age met with some opponents. The most ancient of these were Democritus and Leucippus. They denied the existence of a Deity—asserted that all things were mechanically necessary, and that thought and sense were only modifications of matter. This is atheism in the strictest sense, and the only form of it that has ever been consistently supported. Epicurus followed upon the same principles ; but he rendered the system altogether absurd, by confessing the freedom of the human will. To avoid the imputation of atheism, he asserted the existence of God ; but declared that he resided above the heavens, and interfered not in human affairs. One of his maxims was, that “the blessed and immortal Being neither hath any employment himself, nor troubles himself with others.” Maximus Tyrius* justly observes, that this is rather a description of a Sardanapalus than of a Deity. And some of the moralists† of antiquity remarked, that they knew many men among themselves possessed of active and generous minds, whose characters they valued more highly than that of Epicurus’s god. Some of the ancients also appear to have entertained the following strange notion : They acknowledged the existence of a Supreme and of

* Max.
Tyr. Dis-
sert. 29.
† Cicero de
finibus,
lib. i. and
De Natura
Deorum,
lib. 2.

many inferior deities ; but at the same time, they supposed that there is a certain fate which rules over all, and is superior to the gods themselves. See NECESSITY in Mythology.

The providence exerted by the Author of nature over his works is usually divided into two branches : a *general*, referring to the management of the universe at large ; and a *particular* providence, chiefly regarding particular men.

Upon the first of these, in *The Religion of Nature delineated*, the question is stated somewhat in the following manner : The world may be said to be governed, or at least cannot be said to fluctuate fortuitously, if there are laws or rules by which natural causes act ; if the several phenomena in it succeed regularly, and in general the constitution of things is preserved ; if there are rules observed in the production of herbs, trees, and the like ; if the several kinds of animals are furnished with faculties proper to determine their actions in the different stations which they hold in the general economy of the world ; and, lastly, if rational beings are taken care of in such a manner as will at last agree best with reason. By the providence of God we ought to understand his governing the world by *such* laws as these now mentioned : so that if there are such, there must be a Divine providence.

7
General
provi-
dence.

With regard to *inanimate objects*, the case agrees precisely with the above supposition. The whole of that universe which we see around us is one magnificent and well regulated machine. The world that we inhabit is a large globe, which, conducted by an invisible power, flies with a rapidity of which we have no conception, through an extent of space which sets at defiance every power of fancy to embody it into any distinct image. A large flaming orb stands immovable in the heavens ; around which this, and other worlds of different magnitudes, perform their perpetual revolutions. Hence arise the expected returns of day and night, and the regular diversity of seasons. Upon these great operations a thousand other circumstances depend. Hence, for example, the vapours ascend from the ocean, meet above in clouds, and after being condensed, descend in showers to cover the earth with fertility and beauty. And these appearances are permanent and regular. During every age since men have been placed upon the earth, this astonishing machine continued steadily to perform its complicated operations. Nothing is left to chance. The smallest bodies are not less regular than the largest, and observe continually the same rules of attraction, repulsion, &c. The apparent variations of nature proceed only from different circumstances and combinations of things, acting all the while under their ancient laws. We ourselves can calculate the effects of the laws of gravitation and of motion. We can render them subservient to our own purposes, with entire certainty of success if we only adhere to the rules established by nature, that is to say, by providence.

8
As it re-
spect in-
animate ob-
jects.

Vegetables also live and flourish according to prescribed methods. Each sort is produced from its proper seed ; has the same texture of fibres, is at all times nourished by the *same* kind of juices, digested and prepared by the *same* vessels. Trees and shrubs receive annually their peculiar liveries, and bear their proper fruits : so regular are they in this last respect, that every species may be said to have its profession or trade ap-

9
Vegetables.

Providence

pointed to it, by which it furnishes a certain portion of manufacture, or of food, to supply the wants of animals: being created for the purpose of consumption, all vegetables produce great quantities of seed to supply the necessary waste. Here, too, then, there is evidently a *regulation* by which the several orders are preserved, and the ends of them answered according to their first establishment.

10
Animals,

With regard to *animals*, they too, in structure of their form, are subject to laws similar to those which govern the vegetable world. In the sentient part of their constitution they are no less subject to rule. The lion is always fierce, the fox is crafty, and the hare is timid. Every species retains from age to age its appointed place and character in the great family of nature. The various tribes are made and placed in such a manner as to find proper means of support and defence. Beasts, birds, fishes, and insects, are all possessed of organs and faculties adapted to their respective circumstances, and opportunities of finding their proper food and prey.

11
And man.

Man is subject to the ordinary laws which other material and animal substances obey; but he is left more at large in the determination of his actions. Yet even here things do not fluctuate at random. Individuals do indeed rise and perish according to fixed rules, and nations themselves have only a temporary endurance. But the species advances with a steady progress to intellectual improvement. This progress is often interrupted; but it appears not to be less sure at the long-run than even the mechanical laws which govern the material part of our constitution. Amidst the convulsion of states and the ruin of empires, the useful arts, when once invented, are never lost. These, in better times, render subsistence easy, and give leisure for reflection and study to a greater number of individuals. Tyre and Sydon have passed away, Athens itself has become the prey of barbarians, and the prosperity of ancient Egypt is departed, perhaps for ever; but the ship, the plow, and the loom, remain, and have been perpetually improving. Thus every new convulsion of society does less mischief than the last; and it is hoped that by the assistance of printing the most polished arts and the most refined speculations have now become immortal.

The world is not then left in a state of confusion: it is reduced into order, and methodised for ages to come; the several species of beings having their offices and provinces assigned them. Plants, animals, men, and nations, are in a state of continual change; but successors are appointed to relieve them, and to carry on the *scheme of Providence*.

12
Difficulty
of account-
ing for par-
ticular pro-
vidence,

But the great difficulty is, how to account for that providence which is called *particular*: For rational beings, and free agents, are capable of doing and deserving well or ill; and the safety or danger, that happiness or unhappiness, of a man here, must depend upon many things that seem scarcely *capable* of being determined by Providence. Besides *himself* and his own conduct, he depends upon the conduct of *other men*; whose actions, as we naturally suppose, cannot, consistently with their free will, be controuled for the advantage of another individual. The actions of numbers of men proceeding upon their private freedom, with different degrees of ability, as they cross and impede, or directly

oppose each other, must produce very different effects upon men of different characters, and thus in a strange manner embarrass and entangle the general plan. And as to the *course of nature*, it may justly be asked, is the force of gravitation to be suspended till a good man pass by an infirm building? (See PRAYER.) Add to this, that some circumstances appear absolutely irreconcilable. The wind which carries one into port drives another back to sea; and the rains that are just sufficient upon the hills may drown the inhabitants of the valleys. In short, may we expect *miracles*? or can there be a particular Providence that foresees and prepares for the several cases of individuals, without force frequently committed upon the laws of nature and the freedom of intelligent agents?

In whatever way it is brought about, there is little doubt that something of this kind *must* take place. For as the Deity *does* direct, as already mentioned, the great and general progress of things in this world, he must also manage those of less importance. Nations are composed of individuals. The progress of individuals is the progress of the nation, and the greatest events usually depend upon the history and the most trifling actions of private persons. The difficulty is to conceive how the superintendence and management of all this can be brought about. But as the ways and the thoughts of the Omnipotent Spirit, whose influence pervades, and rules, and animates nature, resemble not the limited operations of men, we can only form conjectures concerning the means by which his government is conducted.

1. In the first place, then, it is not impossible that the Deity should foresee the future actions of intelligent beings. Many of these actions depend upon the mechanism of the material world, which was formed by himself, and must be entirely known to him. Many men among ourselves possess much sagacity in discerning the future actions of others, from attending to their known characters, and the circumstances in which they are placed. If superior natures do exist, and minds more perfect than the human, they must possess this penetration in a more eminent degree in proportion to the excellence of their intellectual powers. But if this discernment be in God proportionable to his nature, as in lower beings it is proportionable to theirs, it then becomes altogether unlimited, and the future actions of free agents are at once unlocked and exposed to his view. Add to this, that the Author of nature is well acquainted with the creatures that he has made; he knows the mechanism of our bodies, the nature and extent of our understandings, and all the circumstances by which we are surrounded. With all these advantages, it is making no great stretch to suppose him capable of discerning the line of conduct which we will pursue; and this even setting aside the infinity of his nature, to which a thousand years are as one day, and supposing him to reason from probabilities in the imperfect manner that we do.

2. There is no impossibility at least, that men, whose characters and actions are thus foreknown, may be introduced into the world in such times and places as that their acts and behaviour may not only coincide with the general plan of things, but may also answer many private cases. The celestial bodies are so placed that their jarring attractions make out a splendid system.

Providence

13.
No good
argument
against its
existence.

14
The Deity
may easily
foresee the
actions of
men;

15
And may
thence fit
them for
their situa-
tions in
life.

Why,

Providence Why then may there not be in the Divine mind something like a projection of the future history of mankind, as well as of the motions of the heavenly bodies? And why should it not be thought possible for men, as well as for them, by some secret law, or rather by the management of an unseen power, to be brought into their places in such a manner as that, by the free use of their faculties, the conjunctions and oppositions of their interests and inclinations, the natural influence of their different degrees of talents, power, and wealth, they may conspire to make out the great scheme of human affairs? There is no absurdity in this supposition: it is not beyond the power of an almighty and perfect Being; and it is worthy of him. Let us take from the Jewish history, as most generally known, an example of what may be supposed to happen daily. It was the intention of providence to place David the son of Jesse upon the throne of the Hebrews. The country is invaded by a foreign enemy: the hostile armies meet, and lie encamped upon opposite mountains. A man comes forth from the army of the invaders, as was extremely common in those times, and defies the Hebrew host to send forth a champion to meet him in single combat. Terrified by the gigantic bulk and mighty force of Goliath, no man would risk the unequal conflict. David, who was too young to carry arms, had been sent to the camp with provisions for his brothers, and heard the challenge. In defence of his flock he had killed some beasts of prey in the wilderness, and he was an excellent marksman with the sling. He thought it might probably be as easy to kill a man as a wild beast; at all events, he knew that a stone well directed would prove no less fatal to a giant than to a dwarf: he therefore resolved to try his skill; and he tried it with success. Here no man's free will was interrupted, and no miracle was accomplished: Yet by this *train* of circumstances thus brought together, a foundation was laid for the future fortunes of the son of Jesse, for the greatness of his country, and for accomplishing the purposes of Providence. According to Seneca, "*Hoc dico, fulmina non mitti a Jove, sed sic omnia disposita, ut ea etiam quæ ab illo non fiunt, tamen sine ratione non fiunt: quæ illius est.—Nam etsi Jupiter illa nunc non facit, facit ut fierent.*"—*I say, that the lightning comes not directly from the hand of Jove, but things are properly disposed for the indirect execution of his will; for he acts not immediately, but by the intervention of means.*

16
The possibility of this exemplified.

17
Secret influences on the mind are far from impossible.

3. Lastly, it is *not impossible* that many things may be accomplished by secret influence, upon the human mind, either by the Deity himself, or by the intervention of agents possessed of powers superior to those which belong to us. "For instance, if the case should require that a particular man be delivered from some threatening ruin, or from some misfortune, which would certainly befall him if he should go such a way at such a time, as he intended: upon this occasion some *new* reasons may be presented to his mind why he should not go *at all*, or not *then*, or not *by that road*; or he may forget

to go. Or, if he is to be delivered from some danger-**Providence** ous enemy, either some new turn given to his thoughts may divert him from going where the enemy will be, or the enemy may be after the same manner diverted from coming where *he* shall be, or his resentment may be *qualified*; or some proper method of *defence* may be suggested to the person in danger. After the same manner advantages and successes may be conferred on the deserving; as, on the other side, men, by way of punishment for their crimes, may incur mischiefs and calamities. These things, and such as these (says Mr Wollaston *), *may be*. For since the motions and actions of men, which depend upon their wills, do also depend upon their judgments, as these again do upon the *present appearances* of things in their minds; if a new prospect of things can be any way produced, the lights by which they are seen *altered*, new forces and directions impressed upon the spirits, passions *exalted* or *abated*, the power of judging *enlivened* or *debilitated*, or the attention taken off without any suspension or alteration of the standing laws of nature,—then, without that, *new* volitions, designs, measures, or a cessation of thinking, may also be produced; and thus many things prevented that otherwise would *be*, and many brought about that would *not*. That there may possibly be such inspirations of new thoughts and counsels (continues our author), may perhaps appear farther from this, that we frequently find thoughts arising in our heads, into which we are led by no discourse, nothing we read, no clue of reasoning, but they surprise and come upon us from we know not what quarter. If they proceeded from the mobility of spirits straggling out of order, and fortuitous affections of the brain, or were they of the nature of *dreams*, why are they not as wild, incoherent, and extravagant as they are?" Is it not much more reasonable to imagine that they come by the order and direction of an all-seeing and all-gracious God, who continually watches over us, and disposes every thing in and about us for the good of ourselves or others? not to speak of the agreeableness of this notion to the opinions of the best and wisest men in all ages (A). "If this, then, be the case, as it seems to be, that men's minds are susceptible of such *insinuations* and *impressions*, as frequently, by ways unknown, do affect them, and give them an inclination towards this or that; how many things (asks our author) may be brought to pass by these means without *fixing* and *refixing* the laws of nature, any more than they are unfixed when one man alters the opinion of another by throwing in his way a book proper for that purpose?"

All this may be effected either by the immediate interposition of God himself, or by that of beings *invisible*, and in nature superior to us, who act as the ministers of his providence. That there are such beings we can hardly doubt, as it is in the highest degree improbable that such imperfect beings as men are at the top of the scale of created existence. And since we ourselves, by the use of our limited powers, do often alter the course

* Religion of Nature delineated, f. 8. 5.

18
And may be effected by beings superior to us, or by the Deity.

(A) That such was the general belief of the Greeks in the days of Homer, is plain from that poet's constantly introducing his deities into the narrative of his poems, and telling us that Minerva, or some other god, altered the minds of his heroes. "By this," says Plutarch, "the poet does not mean to make God *destroy* the will of man, but only move him to will: nor does he miraculously produce the appetites themselves in men, but only causes such imaginations as are capable of exciting them."

Providence of things within our sphere from what they would be if left to the ordinary laws of motion and gravitation, without being said to alter those laws; why may not superior beings do the same as instruments of divine providence? This idea of the intervention of superior natures is beautifully illustrated by Thomson in the following passage:

These are the haunts of meditation, these
The scenes where ancient bards th' inspiring breath,
Ecstatic, felt; and from this world retir'd,
Convers'd with angels and immortal forms,
On gracious errands bent: to save the fall
Of virtue struggling on the brink of vice;
In waking whispers, and repeated dreams,
To hint pure thought, and warn the favoured soul
For future trials fated to prepare.

We agree, however, with Mr Wollaston, in thinking the power of these beings not so large as to alter or suspend the general laws of nature (see MIRACLE); for the world is not like a bungling piece of clock-work, which requires to be often set backwards or forwards. We are likewise perfectly satisfied, that they cannot change their condition, to ape us or inferior beings; and consequently we are not apt hastily to credit stories of *portents*, &c. such as cannot be true, unless the nature of things and their manner of existence were occasionally reversed. Yet as men may be so placed as to become, even by the free exercise of their own powers, *instruments* of God's particular providence to other men; so may we well suppose that these higher beings may be so *distributed* through the universe, and subject to such an economy, unknown to us, as may render *them also* instruments of the same providence; and that they may, in proportion to their greater abilities, be capable, *consistently with the laws of nature*, of influencing human affairs in proper places.

¹⁹ Objections to the doctrine of Providence. We shall next proceed to state some of the chief objections which in ancient or modern times have been brought against the opinion, that the world is governed by a Divine providence.

²⁰ From the imperfections of nature. 1. The first of these is this, that the system of nature contains many imperfections which it ought not to do if it be the work of a perfectly wise and good Being. To avoid the force of this objection, some modern writers have deserted the ground of supreme and absolute goodness, which the ancient theists always occupied, and have asserted that the divine perfection consists in unlimited power and uncontrouled supremacy of will; that consequently the Deity does not always that which is best, but merely what he himself pleases; and that for no other reason but because he *wills* to do so. But this is no better than atheism itself. For it is of no importance to us whether the universe is governed by blind fate or chance, that is to say, by nothing at all; or whether it is governed by an arbitrary sovereign will that is directed by chance, or at least by no principle of beneficence.

²¹ Answered. The true answer to this objection is, that no created system can have every perfection, because it must necessarily be destitute of self-existence and independence; and therefore if beings destitute of some perfections be better than nothing, it was worthy of infinite power and perfect goodness to create such beings. In our present

state, we mortals stand upon too low ground to take a Providence commanding view of the whole frame of things. We can only reason concerning what is unknown from the little that is within our reach. In that little, we can see that wisdom and goodness reign; that nature always aims to produce perfection; that many salutary effects result even from the thunder and the storm: and we doubt not that a view of the whole structure of the universe would afford an additional triumph to the goodness and skill of its great Architect.

We see a regular ascent in the scale of beings from mere lifeless matter up to man; and the probability is, that the scale continues to ascend as far above men in perfection as created beings can possibly be raised.—The sole purpose of God in creating the world must have been to produce happiness: but this would be most effectually done by creating, in the first place, as many of the most perfect class of beings as the system could contain; and afterwards other classes less and less perfect, till the whole universe should be completely full. We do not positively assert such a scheme of creation,

Where all must full, or not coherent be;
And all that rises, rise in due degree,

was actually in the divine Architect's intention; but that it is possible, is sufficiently obvious. No man will pretend to say, that this earth could afford a comfortable subsistence to a greater number of the human race, were all the inferior animals annihilated, than it could at present, swarming as every element is with life.—Suppose then, that as many men had been placed at first upon the earth as it could possibly support, and that matters had been so constituted, as that the number should never have been either increased or diminished; we beg leave to ask, whether, since there would have been evidently room for inferior animals, it would have been most worthy of infinite goodness to leave the whole globe to men, or to introduce into it different orders of less perfect beings, which, while they could not accommodate this principal inhabitant, would each find pleasure in its own existence? To this question different answers cannot surely be given. Let the reader then extend his view, and consider the universe, which, however vast, cannot be positively infinite, as one system as much united as the several parts of this globe; let him suppose that there were at first created as many of the highest order of beings as it could have contained had creation there stopp'd; let him remember that happiness in many different degrees is valuable;—and he will not surely think it any imputation on the goodness of God that there are in the universe many beings far from perfection. The most imperfect of these are by themselves better than nothing; and they all contribute to make up a system which, considered as a whole, we have every reason to believe to be as perfect as any thing not self-existent can possibly be.

2. If the world is conducted by a benevolent providence, how came evil to be introduced into it? This question has perplexed mankind in all ages. The ancient Persians resolved it, by asserting the existence of two gods, Ormazdes the author of good, and Arimanius the author of evil. From them the Christian heretics called *Manichees* borrowed their doctrine of two opposite

²² Objection from the introduction of evil.

Providence opposite co-eternal principles. Both the Platonists and Stoics ascribed the origin of evil to the perverseness or imperfection of matter, which they thought the Deity could not alter; and Pythagoras imagined a state of pre-existence, in which the souls of men had committed offences, for which they are here suffering the punishment. But these hypotheses are, some of them impious, and all unsatisfactory.

23
Answered.

Taking the expression in its most extensive sense, the evils to which the human race are exposed may be reduced to *pain, uneasiness, disappointment of appetites, and death*; of which not one could have been wholly prevented without occasioning greater evils, inconsistent with the perfect goodness of the Creator. As long as we have solid bodies capable of motion, supported by food, subject to the influence of the atmosphere, and divisible, they must necessarily be liable to dissolution or death: But if a man could suffer death, or have his limbs broken, without feeling pain, the human race had been long ago extinct. A fever is a state of the body in which the fluids are in great disorder. Felt we no uneasiness from that disorder, we should have no inducement to pay the proper attention to our state, and should certainly die unawares, without suspecting ourselves to be in danger; whereas, under the present administration of divine providence, the pain and sickness of the disease compel us to have recourse to the remedies proper for restoring us to soundness and to health. Of the uneasinesses to which we are liable, and which are not the effect of immediate pain, the greatest has been sometimes said to arise from the apprehension of death, which constantly stares us in the face, and frequently embitters all our pleasures even in the hour of perfect health.—But this dread of death is implanted in our breasts for the very best of purposes. Had we no horror at the apprehension of death, we should be apt, whenever any misfortune befel us, to quit this world rashly, and rush unprepared into the presence of our Judge: but the horror which attends our reflections on our own dissolution, arising not from any apprehensions of the pain of dying, but from our anxiety concerning our future state of existence, tends strongly to make us act, while we are here, in such a manner as to ensure our happiness hereafter. Add to this, that the fear of death is the greatest support of human laws. We every day see persons breaking through all the regulations of society and good life, notwithstanding they know death to be the certain consequence, and feel all the horrors of it that are natural to man: and therefore were death divested of these horrors, how insignificant would capital punishments be as guardians of the law, and how insecure would individuals be in civil society?

With regard to the unavoidable misfortunes and anxieties of our present state, so far from being truly hurtful in themselves, they are proofs of divine beneficence. When we see men displeased with their situation, when we hear them complain of the difficulties, the miseries, and the cares of life, of the hardships which they have undergone, and the labours which still lie before them; instead of accounting them unfortunate, we ought to regard them as active beings, placed in the only situation that is fit for the improvement of their nature. That discontent, these restless wishes to improve their condition, are so many sure indications that their faculties will not languish. They who are in the least de-

Providence gree accustomed to observe the human character, know well the influence which pleasure and repose have in enfeebling every manly principle, and how capable they are of attaching us even to a sordid and dishonourable existence.

Happy indeed it is for the human race, that the number of those men is small whom providence has placed in situations in which personal activity is unnecessary. By far the greater number are compelled to exert themselves, to mix and to contend with their equals, in the race of fortune and of honour. It is thus that our powers are called forth, and that our nature reaches its highest perfection. It is even perhaps a general truth, that they who have struggled with the greatest variety of hardships, as they always acquire the highest energy of character, so if they have retained their integrity, and have not sunk entirely in the contest, seldom fail to spend their remaining days respectable and happy, superior to passion, and secured from folly by the possession of a wisdom dearly earned.

But the benefits of physical evils have been set in a ²⁴ still stronger light by a great master of moral wisdom, **Physical** who was himself subject to many of those evils. **evil the** That man is a moral agent, sent into this world to acquire **cause of** habits of virtue and piety to fit him for a better state, **moral** is a truth to which no consistent thief will for a moment **good.** refuse his assent. But almost all the moral good which is left among us, is the apparent effect of physical evil.

“Goodness is divided by divines into soberness, righteousness, and godliness. Let it be examined how each ^{Johnston's} of these duties would be practised if there were no ^{Idler, n^o} physical evil to enforce it. 89.

“Sobriety or temperance is nothing but the forbearance of pleasure; and if pleasure was not followed by pain, who would forbear it? We see every hour those in whom the desire of present indulgence overpowers all sense of past, and all foresight of future misery. In a remission of the gout, the drunkard returns to his wine, and the glutton to his feast; and if neither disease nor poverty were felt or dreaded, every one would sink down in idle sensuality, without any care of others, or of himself. To eat and drink, and lie down to sleep, would be the whole business of mankind.

“Righteousness, or the system of social duty, may be subdivided into justice and charity. Of justice, one of the heathen sages has shown, with great acuteness, that it was impressed upon mankind only by the inconveniences which injustice had produced. ‘In the first ages (says he) men acted without any rule but the impulse of desire; they practised injustice upon others, and suffered it from others in their turn: but in time it was discovered, that the pain of suffering wrong was greater than the pleasure of doing it; and mankind, by a general compact, submitted to the restraint of laws, and resigned the pleasure to escape the pain.’

“Of charity, it is superfluous to observe, that it could have no place if there were no want; for of a virtue which could not be practised, the omission could not be culpable. Evil is not only the occasional but the efficient cause of charity; we are incited to the relief of misery by the consciousness that we have the same nature with the sufferer; that we are in danger of the same distresses, and may sometime implore the same assistance.

“Godliness

Providence

"Godliness or piety is elevation of the mind towards the Supreme Being, and extension of the thoughts of another life. The other life is future, and the Supreme Being is invisible. None would have recourse to an invisible power, but that all other subjects had eluded their hopes. None would fix their attention upon the future, but that they are discontented with the present. If the senses were feasted with perpetual pleasure, they would always keep the mind in subjection. Reason has no authority over us but by its power to warn us against evil.

"In childhood, while our minds are yet unoccupied, religion is impressed upon them; and the first years of almost all who have been well educated are passed in a regular discharge of the duties of piety: But as we advance forward into the crowds of life, innumerable delights solicit our inclinations, and innumerable cares distract our attention. The time of youth is passed in noisy frolics; manhood is led on from hope to hope, and from project to project; the dissoluteness of pleasure, the inebriation of success, the ardour of expectation, and the vehemence of competition, chain down the mind alike to the present scene: nor is it remembered how soon this mist of trifles must be scattered, and the bubbles that float upon the rivulet of life be lost for ever in the gulph of eternity. To this consideration scarce any man is awakened but by some pressing and resistless evil; the death of those from whom he derived his pleasures, or to whom he destined his possessions, some disease which shows him the vanity of all external acquisitions, or the gloom of age which intercepts his prospects of long enjoyment, forces him to fix his hopes upon another state; and when he has contended with the tempests of life till his strength fails him, he flies at last to the shelter of religion.

"That misery does not make all virtuous, experience too certainly informs us; but it is no less certain, that of what virtue there is, misery produces far the greater part. Physical evil may be therefore endured with patience, since it is the cause of moral good; and patience itself is one virtue by which we are prepared for that state in which evil shall be no more."

The calamities and the hardships of our present state, then, are so far from being real evils, of which providence ought to be accused, that in every point of view in which we can consider them, they afford the surest proofs of the wisdom of its administration, and of its goodness to man.

The most serious difficulty lies in accounting for the permission of moral evil or guilt, in a system governed by infinite benevolence and wisdom. Those who in a consistent manner hold the doctrine of the absolute necessity of human actions in its full extent and acknowledge all its consequences, find it easy to elude this difficulty. They very fairly deny the existence of any such thing as moral evil in the abstract; and assert, that what we call a *crime*, is nothing more than an action which we always regard with a painful sensation: that these apparent evils endure only for a time; and that all will at last terminate in the perfection and happiness of every intelligent being.

Upon the system of liberty, the shortest answer seems to be this: that some things are absolutely impossible, not from any weakness in the Deity, but because they infer absurdity or contradiction. Thus it is impossible

for twice two to be any thing else than four; and thus it is impossible for Omnipotence itself to confer self-approbation upon an intelligent being who has never deserved it; that is to say, it is impossible for a man of sense to be pleased with himself for having done a certain action, while he himself is conscious that he never did that action. But self-approbation constitutes the highest, the most unmingled, and permanent felicity, of which our nature is capable. It is not in the power of Omnipotence itself, then, to bestow the highest and most permanent felicity of our nature; it must be *earned* and deserved before it can be obtained. In the same manner good desert, virtue or merit, cannot be *conferred*; they must be *acquired*. To enable us to acquire these, we must be exposed to difficulties, and must suffer in a certain degree. If these difficulties had no influence upon our conduct and feelings, if they exposed us to no real danger, no fabric of merit and of self-approbation could be reared upon them. All that the Supreme Being could do for us, was to confer such an original constitution and character as would enable us to do well if we should exert our utmost powers. The universe is not ruled by favour, but by justice. Complete felicity must be purchased. Guilt is an abuse of our freedom, a doing ill where we could have done well, and is entirely the work of man. Heaven could not avoid permitting its existence, and exposing us to danger; for temptation is necessary to virtue, and virtue is the perfection of our nature, our glory, and our happiness.

The permission of moral evil has been so ably accounted for by Simplicius, a Pagan writer, and therefore not biassed by any partiality to the Jewish or Christian Scriptures, that we cannot deny ourselves the pleasure of laying his reasoning before our readers. He asks *, "Whether God may be called the author of sin, because he permits the soul to use her liberty? and answers the question thus:

"He who says that God should not permit the exercise of its freedom to the soul, must affirm one of these two things; either that the soul, though by nature capable of indifferently choosing *good or evil*, should yet be constantly prevented from choosing evil; or else that it should have been made of such a nature as to have no *power* of choosing *evil*.

"The former assertion (continues he) is irrational and absurd; for what kind of liberty would that be in which there should be no freedom of choice? and what choice could there be, if the mind were constantly restrained to one side of every alternative? With respect to the second assertion, it is to be observed (says he), that no evil is in itself desirable, or can be chosen *as evil*. But if this power of determining itself either way in any given case must be taken from the soul, it must either be as something not good, or as some great evil. But whoever saith so, does not consider how many things there are which, though accounted good and desirable, are yet never put in competition with this freedom of will: for without it we should be on a level with the brutes; and there is no person who would rather be a brute than a man. If God then shows his goodness in giving to inferior beings such perfections as are far below this, is it incongruous to the divine nature and goodness to give man a self-determining power over his actions, and to permit him the free exercise of that power?

ed. Salmos.

Providence power? Had God, to prevent man's sin, taken away the liberty of his will, he would likewise have destroyed the foundation of all virtue, and the very nature of man; for there could be no virtue were there not a possibility of vice; and man's nature, had it continued rational, would have been divine, because impeccable. Therefore (continues he), though we attribute to God, as its author, this self-determining power, which is so necessary in the order of the universe; we have no reason to attribute to him that evil which comes by the abuse of liberty: For God doth not cause that aversion from good which is in the soul when it sins; he only gave to the soul such a power as might turn itself to evil, out of which he produces much good, which, without such a power, could not have been produced by Omnipotence itself." So consonant to the doctrine of our scriptures is the reasoning of this opponent of the writings of Moses! *Fas est et ab hoste doceri.*

Objection
from the
apparent
confusion
of human
affairs,

29
Answered,

30
By Plu-
tarch.

The last objection to the belief of a divine providence arises from the apparent confusion of human affairs, that all things happen alike to all, that bad men are prosperous, and that a total want of justice appears to attend the divine administrations. Even the best men have at times been shaken by this consideration.—But there are many reasons for rendering this world a mixed scene: it would become unfit for a state of trial, and of education to virtue were it otherwise.

It has been shown already, that physical evil is the parent of moral good; and therefore it would be absurd to expect that the virtuous should be entirely exempted from that evil. For the occasional prosperity of the wicked, many reasons have been assigned even by those who, in their disquisitions, were not guided by that revelation which has brought to light life and immortality. "God (says Plutarch) spares the wicked, that he may set to mankind an example of forbearance, and teach them not to revenge their injuries too hastily on each other. He spares some wicked men from early punishment, in order to make them instruments of his justice in punishing others. And he spares all for a time, that they may have leisure for repentance; for men (says the same excellent moralist) look at nothing further, in the punishments which they inflict, than to satisfy their revenge and malice, and therefore they pursue those who have offended them with the utmost rage and eagerness; whereas God, aiming at the cure of those who are not utterly incurable, gives them *μετακαταλειθας χρόνος*, "time to be converted."

But this objection receives the best solution from the doctrine of the immortality of the human soul.

———And see!

"Tis come, the glorious morn! the second birth
Of heav'n and earth! awakening nature hears
The *new creating word*, and starts to life,
In every height'ned form, from pain and death
For ever free. *The great eternal scheme*,
Involving all, and in a *perfect whole*
Uniting, as the prospect wider spreads,
To reason's eye cleared up a pace.
Ye vainly wife! Ye blind presumptuous! now,
Confounded in the dust, adore that Pow'r
And Wisdom oft arraign'd: see now the cause,
Why unassuming worth in secret liv'd
And died neglected: why the good man's share

In life was gall and bitterness of soul:
Why the lone widow and her orphans pin'd
In starving solitude; while luxury,
In palaces, lay straining her low thought,
To form unreal wants: why heav'n-born truth,
And moderation fair, wore the red marks
Of superstition's scourge: why licens'd pain,
That cruel spoiler, that embosom'd foe,
Imbitter'd all our bliss. Ye good distressed!
Ye noble few! who here unbending stand
Beneath life's pressure, yet bear up a while,
And what your bounded view, which only saw
A little part, deem'd evil, is no more:
The storms of wintry time will quickly pass,
And one unbounded spring encircle all.

Thompson's Winter.

Providence
||
Provost.

PROVIDENCE-Plantation, with Rhode-island, one of the New-England states, formerly constituting a charter government. Its chief town is Newport.

PROVIDENCE, one of the least of the Bahama islands in the American ocean, but the best of those planted and fortified by the English. It is seated on the east side of the gulph of Florida. W. Long. 77. 35. N. Lat. 25. 0.

PROVINCE, in Roman antiquity, a country of considerable extent, which, upon being entirely reduced under the Roman dominion, was new-modelled according to the pleasure of the conquerors, and subjected to the command of annual governors, sent from Rome; being commonly obliged to pay such taxes and contributions as the senate thought fit to demand.

Of these countries, that part of France next the Alps was one, and still retains the name *Provence*.

Nicod derives the word *a procul vivendo*, "living afar off;" but it is better deduced from *pro* and *vinco* "I overcome."

PROVINCE, in geography, a division of a kingdom or state, comprising several cities, towns, &c. all under the same government, and usually distinguished by the extent either of the civil or ecclesiastical jurisdiction.

The church distinguishes its provinces by archbishoprics; in which sense, England is divided into two provinces, Canterbury and York.

The United Provinces are seven provinces of the Netherlands, who, revolting from the Spanish dominion, made a perpetual alliance, offensive and defensive, at Utrecht, anno 1579. See *UNITED Provinces*.

PROVINCIAL, something relating to a province. It also denotes, in Romish countries, a person who has the direction of the several convents of a province.

PROVISIONS, in a military sense, implies all manner of eatables, food or provender, used in an army, both for man and beast.

PROVOST of a city or town, is the chief municipal magistrate in several trading cities, particularly Edinburgh, Paris, &c. being much the same with mayor in other places. He presides in city-courts, and, together with the bailies, who are his deputies, determines in all differences that arise among citizens.

The provost of Edinburgh is called *lord*, and the same title is claimed by the provost of Glasgow. The former calls yearly conventions of the royal boroughs to Edinburgh by his missives, and is, *ex officio*, president to the convention when met.

See—

Provost
||
Prudence.

PROVOST, or *Prevot-Royal*, a sort of inferior judge formerly established throughout France, to take cognizance of all civil, personal, real, and mixed causes among the people only.

Grand Provost of France, or of the Household, had jurisdiction in the king's house, and over the officers therein; looked to the policy thereof, the regulation of provisions, &c.

Grand Provost of the Constable, a judge who manages processes against the soldiers in the army who have committed any crime.

He has four lieutenants distributed throughout the army, called *provosts of the army*, and particularly provosts in the several regiments.

Provost Marshal of an Army, is an officer appointed to seize and secure deserters, and all other criminals. He is to hinder soldiers from pillaging, to indict offenders, and see the sentence passed on them executed. He also regulates the weights and measures, and the price of provisions, &c. in the army. For the discharge of his office, he has a lieutenant, a clerk, and a troop of marshal-men on horseback, as also an executioner.

There is also a provost-marshal in the navy, who hath charge over prisoners, &c.

The French also had a provost-general of the marines, whose duty it was to prosecute the marines when guilty of any crime, and to make report thereof to the council of war; besides a marine provost in every vessel, who was a kind of gaoler, and took the prisoners into his care, and kept the vessel clean.

Provosts of the Marshals, were a kind of lieutenants of the marshals of France; of these there were 180 seats in France; their chief jurisdiction regarded highwaymen, footpads, house-breakers, &c.

Provost of the Mint, a particular judge instituted for the apprehending and prosecuting of false coiners.

PROVOST, or *Prevot*, in the king's stables; his office is to attend at court, and hold the king's stirrup when he mounts his horse. There are four provosts of this kind, each of whom attends in his turn, monthly.

PROW, denotes the head or fore-part of a ship, particularly in a galley; being that which is opposite to the poop or stern.

PROXIMITY, denotes the relation of nearness, either in respect of place, blood, or alliance.

PRUDENCE, in ethics, may be defined an ability of judging what is best, in the choice both of ends and means. According to the definition of the Roman moralist, *De Officiis*, lib. i. cap. 43. prudence is the knowledge of what is to be desired or avoided. Accordingly, he makes *prudencia* (*De Legibus*, lib. i.) to be a contraction of *providentia*, or foresight. Plato (*De Legibus*, lib. iii.) calls this the leading virtue; and Juvenal, Sat. x. observes,

Nullum munus abest si sit prudentia.

The idea of prudence includes *εὐχέλεια*, or due consultation; that is, concerning such things as demand consultation in a right manner, and for a competent time, that the resolution taken up may be neither too precipitate nor too slow; and *συνεσις* or a faculty of discerning proper means when they occur; and to the perfection of prudence, these three things are farther required, viz. *δαιμονις*, or a natural sagacity; *αγχινοια*, presence of

mind, or a ready turn of thought; and *ἐμπειρία*, or experience the extremes of prudence are craft or cunning on the one hand which is the pursuit of an ill end by direct and proper though not honest means; and folly on the other, which is either a mistake both as to the end and means, or prosecuting a good end by foreign and improper means. *Grove's Moral Philosophy*, vol. ii. chap. ii.

PRUDENTIUS, or AURELIUS PRUDENTIUS CLEMENS, a famous Christian poet, under the reign of Theodosius the Great, who was born in Spain in the year 348. He first followed the profession of an advocate, was afterwards a judge, then a soldier, and at length had an honourable employment at court. We have a great number of his poems, which, from the choice of his subjects, may be termed *Christian Poems*; but the style is barbarous, and very different from the purity of the Augustan age. The most esteemed editions of Prudentius's works are that of Amsterdam, in 1667, with Heinsius's Notes, and that of Paris in 1687, in *usum Delphini*.

PRUNELLA, in botany: A genus of the gymnospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 12th order, *holoraceæ*. The filaments are bifurcated, with an anthera only on one point; the stigma is bifid.

PRUNES, are plums dried in the sunshine, or in an oven.

PRUNING, in gardening and agriculture, is the lopping off the superfluous branches of trees, in order to make them bear better fruit, grow higher, or appear more regular.

Pruning, though an operation of very general use, is nevertheless rightly understood by few; nor is it to be learned by rote, but requires a strict observation of the different manners of growth of the several sorts of fruit-trees; the proper method of doing which cannot be known without carefully observing how each kind is naturally disposed to produce its fruit: for some do this on the same year's wood, as vines; others, for the most part, upon the former year's wood, as peaches, nectarines, &c.; and others upon spurs which are produced upon wood of three, four, &c. to fifteen or twenty years old, as pears, plums, cherries, &c. Therefore, in order to the right management of fruit-trees, provision should always be made to have a sufficient quantity of bearing wood in every part of the trees; and at the same time there should not be a superfluity of useless branches, which would exhaust the strength of the trees, and cause them to decay in a few years.

The reasons for pruning of fruit-trees, are, 1. To preserve them longer in a vigorous bearing-state; 2. To render them more beautiful; and, 3. To cause the fruit to be larger and better tasted.

The general instructions for pruning are as follow. The greatest care ought to be taken of fruit-trees in the spring, when they are in vigorous growth; which is the only proper season for procuring a quantity of good wood in the different parts of the tree, and for displacing all useless branches as soon as they are produced, in order that the vigour of the tree may be entirely distributed to such branches only as are designed to remain. For this reason trees ought not to be neglected in April and May, when their shoots, are produced: however those branches which are intended for bearing the

Prudentius
||
Pruning.

Pruning.

the succeeding year should not be shortened during the time of their growth, because this would cause them to produce two lateral shoots, from the eyes below the place where they were stopped, which would draw much of the strength from the buds of the first shoot: and if the two lateral shoots are not entirely cut away at the winter-pruning, they will prove injurious to the tree. This is to be chiefly understood of stone-fruit and grapes; but pears and apples, being much harder, suffer not so much, though it is a great disadvantage to those also to be thus managed. It must likewise be remarked, that peaches, nectarines, apricots, cherries, and plums, are always in the greatest vigour when they are least maimed by the knife; for where large branches are taken off, they are subject to gum and decay. It is therefore the most prudent method to rub off all useless buds when they are first produced, and to pinch others, where new shoots are wanted to supply the vacancies of the wall; by which management they may be so ordered as to want but little of the knife in winter-pruning. The management of pears and apples is much the same with these trees in summer; but in winter they must be very differently pruned: for as peaches and nectarines, for the most part, produce their fruit upon the former year's wood, and must therefore have their branches shortened according to their strength, in order to produce new shoots for the succeeding year; so, on the contrary, pears, apples, plums, and cherries, producing their fruit upon spurs, which come out of the wood of five, six, and seven years old, should not be shortened, because thereby those buds which were naturally disposed to form these spurs, would produce wood-branches; by which means the trees would be filled with wood, but would never produce much fruit. The branches of standard-trees should never be shortened unless where they are very luxuriant, and, by growing irregularly on one side of the trees, attract the greatest part of the sap, by which means the other parts are either unfurnished with branches, or are rendered very weak; in which case the branch should be shortened down as low as is necessary, in order to obtain more branches to fill up the hollow of the tree: but this is only to be understood of pears and apples, which will produce shoots from wood of three, four, or more years old; whereas most sorts of stone-fruit will gum and decay after such amputations: whenever this happens to stone-fruit, it should be remedied by stopping or pinching those shoots in the spring, before they have obtained too much vigour, which will cause them to push out side-branches; but this must be done with caution. You must also cut out all dead or decaying branches, which cause their heads to look ragged, and also attract noxious particles from the air: in doing of this, you should cut them close down to the place where they were produced, otherwise that part of the branch which is left will also decay, and prove equally hurtful to the rest of the tree; for it seldom happens, when a branch begins to decay, that it does not die quite down to the place where it was produced, and if permitted to remain long uncut, often infects some of the other parts of the tree. If the branches cut off are large, it will be very proper, after having smoothed the cut part exactly even with a knife, chisel, or hatchet, to put on a plaster of grafting clay, which will prevent the wet from soaking into the tree at the wounded part. All such branches as run across each other, and occasion a confusion in the head of the

VOL. XV.

tree, should be cut off; and as there are frequently young vigorous shoots on old trees, which rise from the old branches near the trunk, and grow upright into the head, these should be carefully cut out every year, lest, by being permitted to grow, they fill the tree too full of wood.

As to the pruning of forest-trees, if they be large, it is best not to prune them at all; yet, if there be an absolute necessity, avoid taking off large boughs as much as possible. And, 1. If the bough be small, cut it smooth, close, and sloping. 2. If the branch be large, and the tree old, cut it off at three or four feet from the stem. 3. If the tree grow crooked, cut it off at the crook, sloping upward, and nurse up one of the most promising shoots for a new stem. 4. If the tree grow top-heavy, its head must be lightened, and that by thinning the boughs that grow out of the main branches. But if you would have them spring, rub off the buds, and shroud up the side-shoots. 5. If the side-bough still break out, and the top be able to sustain itself, give the boughs that put forth in spring a pruning after Midsummer, cutting them close.

PRUNUS, in botany: A genus of the monogynia order, belonging to the icosandria class of plants; and in the natural method ranking under the 36th order, *Pomaceæ*. The calyx is quinquefid, inferior; there are five petals; the fruit is a plum, having a kernel with prominent sutures. There are 15 species, of which six are cultivated in Britain: they are originally natives of America and Siberia.

1. The domestica, or common plum-tree, grows 20 or 30 feet high, garnished with oval, spear-shaped leaves, and with the pedunculi for the most part single, terminated by flowers, succeeded by plums of many different colours, sizes, and shapes in the varieties. 2. The infititia, wild-plum, or bullace-tree, grows 12 or 15 feet high; the branches somewhat spinous; the leaves oval, hairy underneath; and the pedunculi by pairs, terminated by white flowers succeeded by small, round, plum-like fruit of different colours in the varieties. 3. The spinosa, black-thorn, or sloe-tree, grows 10 or 12 feet high, very branchy and bushy quite from bottom, armed with strong, sharp spines, small, spear-shaped, smooth leaves, pedunculi growing singly, terminated by flowers, succeeded by small, round, black cherries in autumn. It grows wild everywhere in hedges and woods; and is very proper for planting field hedges, being of very quick and close growth. 4. The cerasus, or common cherry-tree, grows 20 feet or more in height, garnished with oval clusters of lanceolate, smooth leaves, umbellate flowers, succeeded by clusters of red roundish fruit of different sizes and properties in the varieties. Hanbury says, "were this tree scarce, and with much difficulty propagated, every man, though possessed of a single tree only, would look upon it as a treasure; for besides the charming appearance these trees have, when besnowed, as it were, all over with bloom in the spring, can any tree in the vegetable tribe be conceived more beautiful, striking, and grand, than a well-grown and healthy cherry-tree, at that period when the fruit is ripe."

The many kinds of cherry-trees afford an almost endless variety; all differing in some respect in their manner of shooting, leaves, flowers, or fruit: two in particular demand admission into the pleasure-garden; the double-blossomed and the red-flowering. The pleasing show the common cherry-tree makes when in blow is

Pruning.

Pruning.

known to all ; but that of the double-blossomed is much more enchanting. It blossoms like the other in May ; the flowers are produced in large and noble clusters ; for each separate flower is as double as a rose, is very large, and placed on long and slender footstalks, so as to occasion the branches to have an air of ease and freedom. They are of a pure white ; and the trees will be so profusely covered with them, as to charm the imagination. Standards of these trees, when viewed at a distance, have been compared to balls of snow ; and the nearer we approach, the greater pleasure we receive. These trees may be kept as dwarfs, or trained up to standards ; so that there is no garden or plantation to which they will not be suitable. By the multiplicity of the petals the organs of generation are destroyed ; so that those flowers which are really full are never succeeded by any fruit.

The red-flowering cherry-tree differs in no respect from the common cherry-tree, only that the flowers are of a pale-red colour, and by many are esteemed on that account. Besides the ornament and utility afforded us by the flowers and fruit of the cherry, its timber is a further inducement for propagating it ; more especially that of the small black wilding sort ; which may perhaps with propriety be considered as the genuine species, and a native of Britain. Be this as it may, it will grow, in a soil and situation it affects, to be a large timber tree ; which, if taken in its prime before it become tainted at the heart, will turn out perhaps not less than a ton of valuable materials, peculiarly adapted to the purposes of furniture. The grain is fine, and the colour nearly approaching to that of mahogany, to which valuable wood it comes nearer than any other which this country produces. 5. The avium, or great wild-cherry tree, grows 40 or 50 feet high, having oval, spear-shaped leaves, downy underneath, with umbellate sessile clusters of white flowers, succeeded by small round fruit of different properties in the varieties. 6. The padus, or common bird-cherry tree, grows 15 or 20 feet high, of a shrub-like growth, with a spreading head, large, oblong, rough, serrated leaves, having two glands at the back of the base like the other, and with shorter, more compact clusters of flowers, succeeded by large red fruit. This grows wild in hedges in the north parts of England. 7. The Virginiana, or Virginian bird-cherry, grows 30 feet high, dividing into a very branchy head, having a dark purple bark, oval, slightly serrated, shining green leaves, having two glands at the forepart of the base, and long clusters of white flowers, succeeded by small, round, berry-like, black fruit. 8. The Canadensis, or Canada dwarf bird cherry, grows but four or five feet high, branching horizontally near the ground with smooth branches ; broad, spear-shaped, rough downy leaves, without glands ; and long clusters of white flowers, succeeded by small, round, berry-like, black fruit, ripe in autumn. 9. The mahaleb, or perfumed cherry, grows 10 or 15 feet high, with smooth whitish branches, small, oval, shining green leaves, and corymbose clusters of white flowers, succeeded by small fruit. 10. The armeniaca, or apricot tree, grows 20 feet high,

with a large spreading head, having reddish shoots, large nearly heart-shaped leaves, and close-fitting pale-red flowers rising all along the sides of the young branches ; succeeded by large, roundish fruit of a yellow and reddish colour in different varieties. The fruit and the kernels of the *Prunus Siberica*, when eaten, excite a continued head-ach : the kernels, infused in brandy, communicate an agreeable flavour.

Culture. All the different varieties of plums have at first been raised from the stones, and are afterwards preserved by budding and grafting on any plum-stock. The same method is applicable to cherries ; only these are grafted to most advantage upon stocks of the wild black and red cherry raised from the stones of the fruit. The apricot-trees are propagated by budding on any kind of plum-stocks.

PRUSA (anc. geog.), a town situated at mount Olympus in Mysia, built by Prusias, who waged war with Cræsus, (Strabo) ; with Cyrus, (Stephanus) ; both cotemporary princes. Now called *Bursa* or *Prusa*, capital of Bithynia, in Asia Minor. E. Long. 29. 5. N. Lat. 39. 22.

PRUSIAS, the name of several kings of Bithynia.

PRUSIAS, a town of Bithynia, anciently called *Cios*, from a cognominal river, and giving name to the Sinus Cianus of the Propontis ; rebuilt by Prusias the son of Zela, after having been destroyed by Philip the son of Demetrius : it stood on the Sinus Cianus, at the foot of mount Arganthonius. This is the Prusias who harboured Annibal after the defeat of Antiochus.—Of this place was Asclepiades, surnamed *Prusicus*, the famous physician.

PRUSSIA, a modern, but deservedly celebrated kingdom of Europe, whose monarch, along with Prussia Proper, possesses also the electorate of Brandenburg, and some other territories of considerable extent. The district properly called *Prussia* is of great extent, and divided into the Ducal and Regal Prussia, the latter belonging to the republic of Poland till the late partition of the Polish territories. Both together are of great extent ; being bounded on the north by the Baltic, on the south by Poland and the duchy of Mazovia, on the west by Pomerania, and on the east by Lithuania and Samogitia. The name is by some thought to be derived from the *Borussi*, a tribe of the Sarmatians, who, migrating from the foot of the Riphæan mountains, were tempted by the beauty and fertility of the country to settle there. Others think that the name of this country is properly *Porussia* ; *Po* in the language of the natives signifying *near*, and *Porussia* signifying *near Russia*. To the latter etymology we find the king of Prussia himself assenting in the treatise intitled *Memoirs of the House of Brandenburg*. However, it must be owned, that these or any other etymologies of the word are very uncertain, and we find nothing like it mentioned by historians before the tenth century.

The ancient state of Prussia is almost entirely unknown. However, the people are said to have been very savage and barbarous ; living upon raw flesh, and drinking the blood of horses at their feasts, according to Stella, even to intoxication (A). Nay, so extremely

cient inha-
bitants.

(A) This author does not mention any particular method by which they communicated an inebriating quality to the blood of animals. Possibly, however, the vital fluid may have a property of this kind, though unknown in our days where such barbarous customs are disused. Drunkenness from drinking blood is frequently mentioned in Scripture, but whether literally or metaphorically must be decided by the learned.

Prussia.

savage were this people, that they were even unacquainted with the method of constructing huts, and took up their dwelling in caves and cavities of rocks and trees, where they protected themselves and children from the inclemencies of the weather. Among such a people it is vain to expect that any transactions would be recorded, or indeed that any thing worthy of being recorded would be transacted. We shall therefore begin our history of Prussia with the time when the Teutonic knights first got footing in the country. (See *TEUTONIC KNIGHTS*).

Teutonic knights first get footing in the country.

On the expulsion of the Christians from the Holy Land by Saladin, a settlement was given to the Teutonic knights in Prussia by Conrad duke of Mazovia, the competitor of Boleslaus V. for the crown of Poland. Their first residence in this country was Culm; to which territory they were confined by the conditions of the donation, excepting what they could conquer from their pagan neighbours, all which the emperor granted to them in perpetuity.

Encouraged by this grant, the knights conquered the greatest part of the country which now goes by the name of *Prussia*; and, not content with this, became very troublesome to Poland, inasmuch that the monarchs of that kingdom were sometimes obliged to carry on dangerous and bloody wars with them; for an account of which we refer to the article *POLAND*, n° 61. 67, &c.

The Teutonic order continued in Prussia till the year 1531. Their last grand-master was Albert Marquis of Brandenburg, and nephew to Sigismund I. king of Poland. He was preferred to this dignity in hopes that his affinity to Sigismund might procure a restitution of some of the places which had been taken from the order during the former unsuccessful wars with Poland; but in this the fraternity were disappointed. Albert, however, was so far from endeavouring to obtain any favour from his uncle by fair means, that he refused to do homage to him, and immediately began to make preparations for throwing off his dependence altogether, and recovering the whole of Prussia and Pomerania by force of arms. In this he was so far from succeeding, that, being foiled in every attempt, he was forced to resign the dignity of grand-master; in recompence for which, his uncle bestowed on him that part of Prussia now called *Ducal*, in quality of a secular duke. It was now the interest of the house of Brandenburg to assist in the expulsion of the fraternity; and accordingly, being at last driven out of Prussia and Pomerania, they transferred their chapter to Mariendal in Franconia; but in that and other provinces of the empire where they settled, little more than the name of the order once so famous now remains.

Expelled.

History of Brandenburg.

The other most considerable part of his Prussian majesty's dominions is the electorate of Brandenburg. Like other parts of Germany, it was anciently possessed by barbarians, of whom no history can be given. These were subdued by Charlemagne, as is related under the article *FRANCE**; but being on every occasion ready to revolt, in 927 Henry the Fowler established margraves, or governors of the frontiers, to keep the barbarians in awe. The first margrave of Brandenburg was Sigefroy, brother-in-law to the abovementioned emperor; under whose administration the bishoprics of Brandenburg and Havelberg were established by Otho I. From this Sigefroy, to the succession of the house of

* N° 27, &c.

Hohenzollern, from whom the present elector is descended, there are reckoned eight different families, who have been margraves of Brandenburg; namely, the family of the Saxons, of Walbeck, Staden, Plenck, Anhalt, Bavaria, Luxemburg, and Misnia. The margraves of the four first races had continual wars with the Vandals and other barbarous people; nor could their ravages be stopped till the reign of Albert surnamed *the Bear*, the first prince of the house of Anhalt. He was made margrave by the emperor Conrad III. and afterwards raised to the dignity of elector by Frederic Barbarossa, about the year 1100. Some years afterwards the king of the Vandals dying without issue, left the Middle Marche by his last will to the elector, who was besides possessed of the old March, Upper Saxony, the country of Anhalt, and part of Lusatia. In 1332 this line became extinct, and the electorate devolved to the empire. It was then given by the emperor Louis of Bavaria to his son Louis, who was the first of the sixth race. Louis the Roman succeeded his brother; and as he also died without children, he was succeeded by Otho, his third brother, who sold the electorate to the emperor Charles IV. of the house of Luxemburg, for 200,000 florins of gold. Charles IV. gave the Marche to his son Winceslaus, to whom Sigismund succeeded. This elector, being embarrassed in his circumstances, sold the New Marche to the knights of the Teutonic order. Joffe succeeded Sigismund; but aspiring to the empire, sold the electorate to William duke of Misnia; who, after he had possessed it for one year, sold it again to the emperor Sigismund. In 1417, Frederic VI. burgrave of Nuremberg, received the investiture of the country of Brandenburg at the diet of Constance from the hands of the emperor Sigismund; who, two years before, had conferred upon him the dignity of elector, and arch-chamberlain of the Holy Roman empire.

This prince, the first of the family of Hohenzollern, found himself possessed of the Old and Middle Marche, but the dukes of Pomerania had usurped the Marche Ukraine. Against them, therefore, the elector immediately declared war, and soon recovered the province. As the New Marche still continued in the hands of the Teutonic knights, to whom it had been sold as we have already mentioned, the elector, to make up for this, took possession of Saxony, which at that time happened to be vacant by the death of Albert the last elector of the Anhalt line. But the emperor, not approving of this step, gave the investiture of Saxony to the duke of Misnia; upon which Frederic voluntarily desisted from his acquisitions. This elector made a division of his possessions by will. His eldest son was deprived of his right on account of his having too closely applied himself to search for the philosopher's stone; so he left him only Voigtland. The electorate was given to his second son Frederic; Albert, surnamed *Achilles*, had the duchies of Franconia; and Frederic, surnamed *the Fat*, had the Old Marche; but by his death it returned to the electorate of Brandenburg.

Frederic I. was succeeded by his son, called also *Frederic*, and surnamed *Iron-tooth* on account of his strength. He might with as great reason have been surnamed *the Magnanimous*, since he refused two crowns viz. that of Bohemia, which was offered him

Prussia.

Prussia. by the pope, and the kingdom of Poland to which he was invited by the people; but Frederic declared he would not accept of it unless Casimir brother to Ladislaus the late king refused it. These instances of magnanimity had such an effect on the neighbouring people, that the states of Lower Lusatia made a voluntary surrender of their country to him. But as Lusatia was a fief of Bohemia, the king of that country immediately made war on the elector, in order to recover it. However, he was so far from being successful, that, by a treaty of peace concluded in 1462, he was obliged to yield the perpetual sovereignty of Corbus, Peits, Sommerfeld, and some other places to the elector. Frederic then, having redeemed the New Marche from the Teutonic order for the sum of 100,000 florins, and still further enlarged his dominions, resigned the sovereignty in 1469 to his brother Albert, surnamed *Achilles*.

6 **Exploits of Albert surnamed Achilles.** Albert was 57 years old when his brother resigned the electorate to him. Most of his exploits, for which he had the surname of *Achilles*, had been performed while he was burgrave of Nuremberg. He declared war against Lewis duke of Bavaria, defeated, and took him prisoner. He gained eight battles against the Nurembergers, who had rebelled and contested his rights to the burgraviate. In one of these he fought singly against 16 men, till his people came up to his assistance. He made himself master of the town of Griefenburg in the same manner that Alexander the Great took the capital of the Oxydracæ, by leaping from the top of the walls into the town, where he defended himself singly against the inhabitants till his men forced the gates and rescued him. The confidence which the emperor Frederic III. placed in him, gained him the direction of almost the whole empire. He commanded the Imperial armies against Lewis the Rich duke of Bavaria; and against Charles the Bold duke of Burgundy, who had laid siege to Nuis, but concluded a peace at the interposition of Albert. He gained the prize at 17 tournaments, and was never dismounted.

7 **Prussia and Brandenburg united.** All these exploits, however, had been performed before Albert obtained the electorate. From that time we meet with no very important transactions till the year 1594, when John Sigismund of Brandenburg, having married Anne the only daughter of Albert duke of Prussia, this united that duchy to the electorate, to which it has continued to be united ever since; and obtained pretensions to the countries of Juliers, Berg, Cleves, Marck, Ravensburg, and Ravenstein, to the succession of which Anne was heiress.

8 **Unfortunate reign of the elector George William.** Sigismund died in 1619, and was succeeded by his son George William; during whose government the electorate suffered the most miserable calamities. At this time it was that the war commenced between the Protestants and Catholics, which lasted 30 years. The former, although leagued together, were on the point of being utterly destroyed by the Imperialists under the command of Count Tilly and Wallenstein, when Gustavus Adolphus of Sweden turned the scale in their favour, and threatened the Catholic party with utter destruction*. But by his death at the battle of Lutzen, the fortune of war was once more changed. At last, however, peace was concluded with the emperor; and, in 1640, the elector died, leaving his do-

* See Sweden.

minions to his son Frederic William, surnamed the *Great*.

This young prince, though only 20 years of age at the time of his accession, applied himself with the utmost diligence to repair the losses and devastations occasioned by the dreadful wars which had preceded. He received the investiture of Prussia personally from the king of Poland, on condition of paying 100,000 florins annually, and not making truce or peace with the enemies of that crown. His envoy likewise received the investiture of the electorate from the emperor Ferdinand III. The elector then thought of recovering his provinces from those who had usurped them. He concluded a truce for 20 years with the Swedes, who evacuated the greatest part of his estates. He likewise paid 140,000 crowns to the Swedish garrisons, which still possessed some of his towns; and he concluded a treaty with the Hessians, who delivered up a part of the duchy of Cleves; and obtained of the Hollanders the evacuation of some other cities.

In the mean time, the powers of Europe began to be weary of a war which had continued for such a length of time with such unrelenting fury. The cities of Osnaburg and Munster being chosen as the most proper places for negotiation, the conferences were opened in the year 1645; but, by reason of the multiplicity of business, they were not concluded till two years after. France, which had espoused the interests of Sweden, demanded that Pomerania should be ceded to that kingdom as an indemnification for the expences which the war had cost Gustavus Adolphus and his successors. Although the empire and the elector refused to give up Pomerania, it was at last agreed to give up to the Swedes Hither Pomerania, with the isles of Rugen and Wollin, also some cities; in return for which cession, the bishoprics of Halberstadt, Minden, and Camin, were secularized in favour of the elector, of which he was put in possession, together with the lordships of Hohenstein and Richenstein, with the reversion of the archbishopric of Magdeburg. This was the treaty of Westphalia concluded in 1648, and which serves as a basis to all the possessions and rights of the German princes. The elector then concluded a new treaty with the Swedes, for the regulation of limits, and for the acquittal of some debts, of which Sweden would only pay a fourth; and next year the electorate, Pomerania, and the duchies of Cleves, were evacuated by the Swedes.

Notwithstanding all these treaties, however, the Swedes soon after invaded Pomerania, but were entirely defeated by the elector near the town of Fehrbellin. Three thousand were left dead on the spot, among whom were a great number of officers; and a great many were taken prisoners. The elector then pursued his victory, gained many advantages over the Swedes, and deprived them of the cities of Stralsund and Gripswald. On this the Swedes, hoping to oblige the elector to evacuate Pomerania, which he had almost totally subdued, invaded Prussia, from Livonia, with 16,000 men; and advancing into the country, they burned the suburbs of Memel, and took the cities of Tilte and Insterburg. The elector, to oppose the invaders, left Berlin on the 10th of January 1679, at the head of 9000 men. The Swedes retired at his approach, and were greatly harassed by the

9 **Reign of Frederic William the Great.**

10 **Treaty of Westphalia concluded.**

11 **The elector succeeds against the Swedes.**

Prussia. the troops on their march. So successful indeed was the elector on this occasion, that the Swedes lost almost one half of their army killed or taken prisoners. At last, having crossed the bay of Frisch-haff and Courland on the ice, he arrived on the 19th of January, with his infantry, within three miles of Tilse, where the Swedes had their head-quarters. The same day, his general, Trefenfeldt, defeated two regiments of the enemy near Splitter; and the Swedes who were in Tilse abandoned that place, and retired towards Courland. They were pursued by General Gortz, and entirely defeated with such slaughter, that scarce 3000 of them returned to Livonia. Yet, notwithstanding all these victories, the elector being pressed on the other side by the victorious generals of France, M. Turenne and the prince of Conde, was obliged to make peace with the Swedes. The conditions were, that the treaty of Westphalia should serve for a basis to the peace; that the elector should, have the property of the customs in all the ports of Further Pomerania, with the cities of Camin, Gartz, Grieffenburg, and Wildenbruck: on his part, he consented to give up to the Swedes all that he had conquered from them, and to give no assistance to the king of Denmark, upon condition that France delivered up to him his provinces in Westphalia, and paid him 300,000 ducats, as an indemnification for the damages done by the French to his states. This treaty was styled *the peace of St Germain*.

¹²

¹³
A strange
embassy
from the
cham of
Tartary.

With the treaty of St Germain terminated the military exploits of Frederic William, who passed the last years of his administration in peace. His great qualities had rendered him respected by all Europe, and had even been heard of in Tartary. He received an embassy from Murad Geray, cham of the Tartars, courting his friendship. The barbarian ambassador appeared in such tattered clothes as scarce covered his nakedness, so that they were obliged to furnish him with other clothes before he could appear at court. His interpreter had a wooden nose and no ears. In 1684, Frederic received into his dominions great numbers of Protestants who fled out of France from the persecutions of Louis XIV. after he had revoked the edict of Nantz. Twenty thousand of them are said to have settled at this time in the electorate, where they introduced new arts and manufactures, that were of the utmost benefit to the country. By this, however, he disobligeed Louis XIV. for which reason he concluded an alliance with the emperor; and having furnished him with 8000 troops against the Turks in Hungary, the emperor yielded to him the circle of Schwibus in Silesia, as an equivalent for all his rights in that province.

¹⁴
Frederic
III. obtains
the title of
king of
Prussia.

In 1688, the elector Frederic William died, and was succeeded by his son Frederic III. This prince was remarkably fond of show and ceremony, which, during the course of his government, involved him in much expence. The regal dignity seemed to be the greatest object of his ambition. To obtain this, he joined with the emperor in the alliance against France, in which he was engaged by William III. king of Britain. He also yielded up the circle of Schwibus, which had been given to his predecessor; and, in 1700, obtained from the emperor that dignity which he had so earnestly desired. The terms on which it was ob-

tained were, 1. That Frederick should never separate from the empire those provinces of his dominions which depended on it. 2. That he should not, in the emperor's presence, demand any other marks of honour than those which he had hitherto enjoyed. 3. That his Imperial majesty, when he wrote to him, should only give him the title of *Royal Dilection*. 4. That nevertheless the ministers which he had at Vienna should be treated like those of other crowned heads. 5. That the elector should maintain 6000 men in Italy at his own expence, in case the emperor should be obliged to make war on account of the succession of the house of Bourbon to the crown of Spain. 6. That those troops should continue there as long as the war lasted.

Thus was the kingdom of Prussia established through the friendship of the emperor, with whom Frederic I. so called as being the first king of Prussia, continued all his life in strict alliance. Indeed he was a pacific prince and though contemptible in his person, and incapable of achieving great things, had this merit, that he always preserved his dominions in peace, and thus consulted the true interest of his subjects much more than those monarchs who have dazzled the eyes of the world by their military exploits. He was indeed vain, and fond of show, as we have already observed; but had a good heart, and is said never to have violated his conjugal vow; though it does not appear that he was greatly beloved by his royal consorts (of whom he had three) on that or any other account.

Frederic I. died in the beginning of 1713, and was succeeded by Frederic William. He was in almost every thing the reverse of his father. His dispositions were altogether martial; so that he applied himself entirely to the augmentation of his army, and perfecting them in their exercise, by which means they became the most expert soldiers in Europe. His foible was an ambition of having his army composed of men above the ordinary size; but as these could not be procured, he composed a regiment of the tallest men he could find; and as his officers made no scruple of picking up such men wherever they could find them for his majesty's use, the neighbouring states were frequently offended, and a war was often likely to ensue even from this ridiculous cause. However, his Prussian majesty was never engaged in any martial enterprise of consequence: but having put his army on the most respectable footing of any in the world, and filled his coffers, for he was of a very saving disposition, he put it in the power of his son to perform those exploits which have been matter of astonishment to all Europe.

It was in this king's reign that Prussia first perceived her natural enemy and rival to be the house of Austria, and not France as had been formerly supposed. Hence frequent bickerings took place between these two powers, for which the persecution of the Protestants by some of the catholic states of the empire afforded a pretence; and though a war never actually took place, yet it was easy to see that both were mortal enemies to each other. But when Frederic William died in 1740, this enmity broke out in full force. The empress queen was then left in a very disagreeable situation, as has been observed under the article Britain, n° 410, &c. Of this Frederic II. took the advantage to do himself justice, as he said, with regard

18
Combina-
tion against
him. The treaty was hardly concluded with the king of Prussia, by which she reluctantly yielded up the province of Silesia, and with it a clear revenue of L. 800,000 a-year, before she entered into another with the court of Petersburg, which was concluded May 22. 1746. This treaty, as far as it was made public, was only of a defensive nature; but six secret and separate articles were added to it. By one of these it was provided, that in case his Prussian majesty should attack the empress-queen, or the empress of Russia, or even the republic of Poland, it should be considered as a breach of the treaty of Dresden, by which Silesia was given up. It was also stipulated, that, notwithstanding that treaty (which indeed had been dictated by the king of Prussia himself), the right of the empress-queen to Silesia still continued, and for the recovery of that province the contracting powers should mutually furnish an army of 60,000 men. To this treaty, called the treaty of *Petersburg*, the king of Poland was invited to accede; but he, being in a manner in the power of the king of Prussia, did not think proper to sign it: however, he verbally acceded to it in such a manner, that the other parties were fully convinced of his design to co-operate with all their measures; and in consideration of this intention, it was agreed that he should have a share in the partition of the king of Prussia's dominions, in case of a successful event of their enterprises.

19
He invades
Saxony. In consequence of these machinations, every art was used to render the king of Prussia personally odious to the empress of Russia; the queen of Hungary made vast preparations in Bohemia and Moravia; and the king of Poland, under pretence of a military amusement, drew together 16,000 men, with whom he occupied a strong post at Pirna. The queen of Hungary, still further to strengthen herself, concluded a treaty with the court of France at Versailles, dated May 1. 1756. But in the mean time, the king of Prussia having understood by his emissaries what was going forward, resolved to be beforehand with his enemies, and at least to keep the war out of his own country; and therefore entered Saxony with a considerable army. At first he affected only to demand a free passage for his troops, and an observance of the neutrality professed by the king of Poland; but, having good reasons to doubt this neutrality, he demanded, as a preliminary, that these Saxon troops should immediately quit the strong post they occupied, and disperse themselves. This demand was refused; on which his Prussian majesty blockaded the Saxon camp at Pirna, resolving to reduce it by famine, since its strong situation rendered an attack very dangerous. At that time there were in Bohemia two Saxon armies, one under the command of M. Brown, and the other under M. Piccolomini. To keep these in awe, the king had sent M. Schwerin with an army into Bohemia from the country of Glatz, and M. Keith had penetrated into the same kingdom on the side of Misnia. But still the king of Prussia did not entirely confide in these dispositions;

and therefore fearing least M. Brown might afford some assistance to the Saxons, he joined his forces under Keith, and on December 1. attacked and defeated the Austrian general, so that the latter found it impossible to relieve the Saxons, who, after a vain attempt to retire from their post, were all taken prisoners. The king of Poland quitted his dominions in Germany, and the Prussians took up their winter-quarters in Saxony. Here they seized on the revenues, levied exorbitant contributions, and obliged the country to furnish them with recruits. The king of Prussia at this time made himself master of the archives of Dresden, by which means he procured the originals of those pieces abovementioned, which, when produced to the world, gave a full proof of the combination that had been formed against him, and consequently justified the measures he had taken for his own defence.

No sooner had the king entered Saxony, in the manner already related, than a process was commenced against him in the emperor's Aulic council, and before the diet of the empire, where he was soon condemned for contumacy, and put to the ban of the empire.—The various circles of the empire were ordered to furnish their contingents of men and money to put this sentence in execution; but these came in so slowly, that, had it not been for the assistance of the French under the prince de Soubise, the army would probably have never been in a condition to act. The Austrians, in the mean time, made great preparations, and raised 100,000 men in Bohemia, whom they committed to the care of prince Charles of Lorraine, assisted by M. Brown. The Czarina sent a body of 60,000 men under M. Apraxin, to invade the Ducal Prussia; whilst a strong fleet was equipped in the Baltic, in order to co-operate with that army. The king of Sweden also acceded to the confederacy, in hopes of recovering the possessions in Pomerania which his ancestors had enjoyed; and the duke of Mecklenburg took the same party, promising to join the Swedish army with 6000 men as soon as it should be necessary. On the king of Prussia's side appeared nobody excepting an army of between 30,000 and 40,000 Hanoverians commanded by the duke of Cumberland; and these were outnumbered and forced to yield to a superior army of French commanded by M. D'Etrees.

21
He invades
Bohemia,
and totally
defeats the
Austrian
army. In the mean time, his Prussian majesty, finding that he must depend for assistance solely on his own abilities, resolved to make the best use of his time. Accordingly, in the spring 1757, his armies poured into Bohemia from two different quarters, while the king himself prepared to enter it from a third. M. Schwerin entered from Silesia; the prince of Bevern from Lusatia, where he defeated an army of 28,000 Austrians that opposed his passage. As the intentions of the king himself were not known, the Austrians detached a body of 20,000 men from their main army to observe his motions. This was no sooner done than the king cut off all communication between the detachment and the main body; and having joined his two generals with incredible celerity, he engaged the Austrians near Prague, totally defeated them, took their camp, military chest, and cannon; but lost the brave general Schwerin, who was killed at the age of 82, with a colonel's standard in his hand. and bom-
bards
Prague.

About 40,000 of the Austrian army took refuge in Prague, while the rest fled different ways. The city was instantly invested by the king, and all succours were cut off. The great number of troops which it contained rendered an attack unadvisable, but seemed to render the reduction of it by famine inevitable; however, the king, to accomplish his purpose the more speedily, prepared to bombard the town. On the 29th of May, after a most dreadful storm of thunder and lightning, four batteries began to play on the city. From these were thrown, every 24 hours, 288 bombs, besides a vast number of red-hot balls, so that it was soon on fire in every quarter. The garrison made a vigorous defence, and one well-conducted sally; but had the misfortune to be repulsed with great loss. The magistrates, burghers, and clergy, seeing their city on the point of being reduced to an heap of rubbish, supplicated the commander in the most earnest manner to capitulate; but he was deaf to their intreaties, and drove 12,000 of the most useless mouths out of town, who were quickly driven in again by the Prussians.

25
Count
Daun takes
the com-
mand of
the Au-
strian ar-
my.

Thus the affairs of the empress-queen seemed verging to destruction, when Leopold count Daun took upon him the command of the remains of M. Brown's army. This general had arrived within a few miles of Prague the day after the great battle. He immediately collected the scattered fugitives with the greatest diligence, and retired with them to a strong post in the neighbourhood, from whence he gave the troops in Prague hopes of a speedy relief. It was now the king of Prussia's business, either to have attempted to make himself master of the city by one desperate effort, or entirely to have abandoned the enterprise, and driven count Daun from his post before his troops had recovered from the terror of their late defeat; but, by attempting to do both, he rendered himself incapable of doing either. Though the army of count Daun already amounted to 50,000 men, and though they were strongly entrenched, and defended by a vast train of artillery, his majesty thought proper to send no more than 32,000 men. This body made the arduous attempt on the 18th of June; but though they did all that human courage and conduct could do, and though the king himself at last charged at the head of his cavalry, the Prussians were driven out of the field with great loss. This engagement was named *the battle of Colin*.

27
Siege of
Prague
raised.

The first consequence of the battle of Colin was, that the king of Prussia was obliged to raise the siege of Prague; soon after which, he was obliged to quit Bohemia, and take refuge in Saxony. The Austrians harassed him as much as possible; but, notwithstanding their great superiority, their armies were not in a condition to make any decisive attempt upon him, as the frontiers of Saxony abounded with situations easily defended. In the mean time, the Russians, who had hitherto been very dilatory in their motions, began to exert themselves, and enter Ducal Prussia, under M. Apraxin and Fermor, where they committed innumerable cruelties and excesses. A large body of Austrians entered Silesia, and penetrated as far as

Breslau. Then they made a turn backwards, and besieged Schweidnitz. Another body entered Lusatia, and made themselves masters of Zittau. An army of 22,000 Swedes entered Prussian Pomerania, took the towns of Anclam and Demmein, and laid the whole country under contribution. The French, too, being freed from all restraint by the capitulation of the duke of Cumberland at Closter Seven, made their way into Halberstadt and the Old Marche of Brandenburg, first exacting contributions, and then plundering the towns. The army of the empire, being reinforced by that of the prince de Soubise, after many delays, was on full march to enter Saxony, which left the Austrians at liberty to exert the greatest part of their force in the reduction of Silesia. General Haddick penetrated through Lusatia, passed by the Prussian armies, and suddenly appeared before the gates of Berlin, which city he laid under contribution. He retired on the approach of a body of Prussians; yet he still found means to keep such a post as interrupted the king's communication with Silesia. The destruction of the king of Prussia therefore now seemed inevitable. Every exertion which he had made, though brave and well-conducted, had been unsuccessful. His general Lehwald, who opposed the Russians, had orders to attack them at all events. He obeyed his orders; and with 30,000 men attacked 60,000 of the enemy strongly entrenched at a place called *Norkitten*. The Prussians behaved with the greatest valour; but after having killed five times more of the enemy than they themselves lost, they were obliged to retire, though more formidable after their defeat than the Russians after their victory. The king, in the mean time, exerted himself on every side, and his enemies fled everywhere before him; but whilst he pursued one body, another gained upon him in some other part, and the winter came on fast, while his strength decayed, and that of his adversaries seemed to increase on every quarter.

The Prussian monarch, however, though distressed, did not abandon himself to despair, or lose that wonderful presence of mind which has so eminently distinguished him in all his military enterprises. He industriously delayed a decisive action till the approach of winter; but at last, after various movements, on November 5. 1757, he met at Rosbach with the united army of his enemies commanded by the prince of Saxe-Hilburghausen and the prince de Soubise. The allied army amounted to 50,000 men complete; but most of the troops of the Circles were new-raised, and many of them not well affected to the cause. The Prussians did not exceed 25,000 men; but they were superior to any troops in the world, and were inspired, by the presence of their king, with the most enthusiastic valour. The Austrians were defeated with the loss of 3000 killed, eight generals, 250 officers of different ranks, and 6000 private soldiers, taken prisoners, while night alone prevented the total destruction of the army.

By this battle the king was set free on one side; but this only gave him an opportunity of renewing his labours on another. The Austrians had a great force, and now began to make a proportionable progress in Silesia. After a siege of 16 days, they had reduced the strong fortrefs of Schweidnitz, and obliged

the Prussian garrison of 4000 men to surrender prisoners of war. Hearing then of the victory at Rosbach, and that the king of Prussia was in full march to relieve Silesia, they resolved to attack the Prince of Bevern in his strong camp under the walls of Breslau. They attacked the Prince's army on November 22d; but their attack was sustained with the greatest resolution. The slaughter of the Austrians was prodigious. A great part of the enemy had retired from the field of battle, and the rest were preparing to retire, when all at once the Prussian generals took the same resolution. Their army had suffered much in the engagement, and they became apprehensive of a total defeat in case their entrenchments should be forced in any part; for which reason they quitted their strong post, and retired behind the Oder. Two days after, the prince of Bevern, going to reconnoitre without escort, attended only by a groom, was taken prisoner by an advanced party of Croats, a small body of whom had crossed the Oder.

On this the town of Breslau immediately surrendered; where, as well as at Schweidnitz, the Austrians found great quantities of provisions, ammunition, and money. All Silesia was on the point of falling into their hands, and the Prussian affairs were going into the utmost distraction, when the king himself by a most rapid march passed through Thuringia, Misnia, and Lusatia, in spite of the utmost efforts of the generals Haddick and Marshall, who were placed there to oppose him; and, entering Silesia on the 2d of December, joined the prince of Bevern's corps, who passed the Oder to meet him. The garrison of Schweidnitz, who, as we have already observed, had been made prisoners of war, also joined the king's army unexpectedly; and their presence contributed not a little, notwithstanding the smallness of their number, to raise the spirits of the whole army. They had submitted to the capitulation with the greatest reluctance; but as the Austrians were conducting them to prison, they happened to receive intelligence of the victory at Rosbach: on which they immediately rose on the escort that conducted them, and entirely dispersed it; and afterwards marching in such a direction as they thought might most readily lead them to their king, they accidentally fell in with his army.

His Prussian majesty now approached Breslau; on which the Austrians, confiding in their superiority, (for they exceeded 70,000, while the Prussians scarce amounted to 36,000), abandoned their strong camp, the same which the prince of Bevern had formerly occupied, and advanced to give him battle. The king did not intend by any means to disappoint them, but advanced on his part with the greatest celerity. The two armies met on December 5th, near the village of Leuthen. Count Daun made the best dispositions possible. The ground occupied by his army was a plain, with small eminences in some parts. These eminences they surrounded with artillery; and as the ground was also interspersed with thickets, they sought to turn these likewise to their advantage. On their right and left were hills, on which they planted batteries of cannon. The ground in their front was intersected by many causeways; and to make the whole more impracticable, the Austrians had felled a great number of trees, and scattered them in the way. It was almost

impossible at the beginning of the engagement for the Prussian cavalry to act, on account of these impediments; but, by a judicious disposition made by the king himself, all difficulties were overcome. His majesty had placed four battalions behind the cavalry of his right wing; foreseeing that General Nadaſti, who was placed on the enemy's left with a corps de reserve, designed to attack him in flank. It happened as he had foreseen: that general's cavalry attacked the Prussian right wing with great fury; but he was received with such a severe fire from the four battalions, that he was obliged to retire in disorder. The king's flank then, well covered and supported, was enabled to act with such order and vigour as repulsed the enemy. The Austrian artillery was also silenced by that of the Prussians; however, the Austrians continued to make a gallant resistance during the whole battle. After having been once thrown into disorder, they rallied all their forces about Leuthen, which was defended on every side by entrenchments and redoubts. The Prussians attacked them with the utmost impetuosity, and at last became masters of the post; on which the enemy fled on all sides, and a total rout ensued. In this battle the Austrians lost 6000 killed on the spot, 15,000 taken prisoners, and upwards of 200 pieces of cannon.

The consequences of this victory were very great. Breslau was immediately invested, and surrendered on December 29th; the garrison, amounting to 13,000 men, were made prisoners of war. The blockade of Schweidnitz was formed as closely as the season of the year would permit; while detached Prussian parties over-ran the whole country of Silesia, and reduced every place of less importance. The Russians, who had ravaged and destroyed the country in such a manner that they could not subsist in it, thought proper to retire out of the Prussian dominions altogether. Thus General Lehwald was left at liberty to act against the Swedes; and them he quickly drove out of Prussian Pomerania, the whole of which country he not only recovered, but also some part of Swedish Pomerania. Thus the duchy of Mecklenburg being left quite exposed, the king took ample vengeance on it by exacting the most severe contributions of men and money. To complete this monarch's good fortune also, the French, who had retired after the battle of Rosbach, were now opposed by the Hanoverians under Prince Ferdinand, who kept them so well employed, that, during the rest of the war, the king of Prussia had no more trouble from them. See BRITAIN, n^o 442.

The beginning of the year 1758 was favourable to the arms of his Prussian majesty. On the 3d of April he commenced his operations against Schweidnitz, and pushed the siege so vigorously, that the place surrendered in 13 days. He then disposed his forces in such a manner as might best guard his dominions against his numerous enemies. For this purpose count Dohna commanded a body of troops on the side of Pomerania; another considerable body was posted between Wohlau and Glogau, in order to cover Silesia from the Russians, in case they should make their inroad that way. An army, in a little time after, was formed in Saxony, commanded by the king's brother Prince Henry. This army consisted of 30 battalions and 45 squadrons, and was designed to make head against the army of the empire; which, by great efforts

Prussia. forts made during the winter, and the junction of a large body of Austrians, was again in a condition to act. Between all these armies a ready communication was kept up by a proper choice of posts. After the reduction of Schweidnitz, the king having made a show of invading Bohemia, suddenly burst into Moravia, where in a short time he made himself master of the whole country, and on the 27th of May laid siege to Olmutz the capital. Of this M. Daun was no sooner informed, than he took his route to Moravia through Bohemia: and, though he was not in a condition to risk a battle, nor indeed would have done so unless he had had a very considerable advantage; yet, by placing himself in a strong situation where he could not be attacked, by harassing the king's troops and cutting off their convoys, he at last obliged him to abandon the enterprise. The king, however, who frequently owed a good part of his success to the impenetrable secrecy with which he covered all his designs, gave not the least hint of his intention to raise the siege of Olmutz. On the contrary, the very day before the siege was raised, the firing continued as brisk as ever; but in the night (July 1.) the whole army took the road to Bohemia in two columns, and gained an entire march upon the Austrians. Thus, notwithstanding the utmost efforts of his enemies, the Prussian army reached Bohemia with very little molestation. Here he seized upon a large magazine at Lieutomissel; defeated some corps of Austrians who had attempted to interrupt his progress; and arrived at Konigsgratz, of which he took possession, after driving from it 7000 Austrians who were entrenched there. This city and several other districts he laid under contribution: but soon after entered Silesia, and marched with the utmost rapidity to encounter the Russians, who had at that time united their forces under generals Brown and Fermor, entered the New Marche of Brandenburg, and laid siege to Cultrin.

40
The Rus-
sians be-
siege Cu-
ltrim.

The king arrived at this city at a very critical period. The Russians had laid siege to it on the 15th of August; and though they were not well skilled in managing artillery, yet, by furious and unremitting discharges at random, they threw in such a number of bombs and red-hot balls, that the town was soon on fire in every quarter. Some of the wretched inhabitants were burned; others buried in the ruins of their houses, or killed by the balls which fell like hail in the streets; while many of the survivors abandoned their habitations, and fled out of the town on that side where it was not invested. The governor did every thing for the defence of the place; but as the walls were built after the old manner, it was impossible that the town could have made a defence for any length of time, especially as the principal magazine of the besieged had been blown up. The avenger of all these injuries, however, was now at hand. The king came in sight of the Russians on the 25th of August, after a march of 56 days, and beheld the country everywhere desolated, and the villages in flames by the depredations of his cruel enemy, who had raised the siege at his approach, and retired towards a neighbouring village named Zorndorff. At nine o'clock in the morning, a most terrible fire of cannon and mortars poured destruction on the right wing of the Russian army for two hours without intermission. The slaughter was such as might

41
But are de-
feated at
Zorndorff.

have been expected; but the Russians kept their ground with astonishing resolution, new regiments still pressing forward to supply the places of those that fell. When the first line had fired away all their charges, they rushed forward on the Prussians with their bayonets; and all at once these brave troops, though encouraged by the presence of their king, gave way and fled before an enemy already half defeated. The Russian generals ought now to have attacked with their cavalry the disordered infantry of their enemies, which would have completed the defeat, and in all probability given the finishing stroke to the king of Prussia's affairs. This opportunity, however, they lost: but the king was not so negligent; for, by a very rapid and masterly motion, he brought all the cavalry of his right wing to the centre, and falling on the Russian foot uncovered by their horse, and even disordered by their own success, they pushed them back with most miserable slaughter, at the same time that the repulsed battalions of infantry, returning to the charge, and exasperated at their late disgrace, rendered the victory no longer doubtful. The Russians were now thrown into the most dreadful confusion. The wind blew the dust and smoke into their faces, so that they could not distinguish friends from foes; they fired on each other, plundered their own baggage which stood between the lines, and intoxicated themselves with brandy: the ranks fell in upon one another; and, being thus crammed together into a narrow space, the fire of the Prussians had a full and dreadful effect, while their enemies kept up only a scattered and ineffectual fire, generally quite over their heads. Yet even in this dismal situation the Russians did not fly; but suffered themselves to be slaughtered till seven at night, when their generals having caused an attack to be made on the Prussian right wing, the attention of the enemy was drawn to that quarter, and they had time to retire a little from the field of battle to recover their order.

In this engagement, which was called the *battle of Zorndorff*, the Russians lost 21,529 men, while that of the Prussians did not exceed 2000. A vast train of artillery was taken, together with the military chest, and many officers of high rank. The consequence was, that the Russian army retreated as far as Landsberg on the frontiers of Poland, and the king was left at liberty to march with his usual expedition to the relief of prince Henry of Saxony.

The Prince was at this time sorely pressed by M. Daun. As soon as the king had left Bohemia in the manner already related, M. Daun, considering that it would have been to no purpose to follow him, resolved to turn his arms towards Saxony. Towards that country, therefore, he took his route through Lusatia, by Zittau, Gorlitz, and Bautzen. On the 3d of September he invested the strong fortress of Sonnenstein; which unaccountably surrendered, after a single day's resistance, to one of his generals named *Macquire*. He then began to favour the operations of General Laudohn, who had advanced through the Lower Lusatia to the confines of Brandenburg; and, by drawing the attention of the Prussian forces which were left in Silesia to the northward of that duchy, he facilitated the progress of the generals Harsch and De Ville in the southern parts. He then proposed that prince Henry should be attacked by the army of the empire, while that of

the king of
Prussia;

the Austrians should pass the Elbe, and, falling at the same time on the Prussians, second the attack of the Imperialists, and cut off the retreat of their enemies from Dresden. The sudden appearance of the king of Prussia, however, put an end to this plan; general Laudohn abandoned, all his conquests in lower Lusatia, and retired towards M. Daun, while that general himself retired from the neighbourhood of Dresden as far as Zittau. The army of the empire only kept its ground; possessing itself of the strong post at Pirna, formerly mentioned, but did not undertake any thing. As for the Swedes, who had directed their motions by those of the Russians, they no sooner heard of the victory of Zorndorff, than they retreated with much more expedition than they had advanced.

Thus the king of Prussia's affairs seemed to be pretty well retrieved, when by one fatal piece of negligence he was brought to the verge of ruin. M. Daun had possessed himself of an advantageous camp at Stolphen, by which he preserved a communication with the army of the empire. On the other hand, the king of Prussia, having taken possession of an important post at Bautzen, extended his right wing to the village of Hochkirchen, by which he preserved a communication with his brother Prince Henry, protected Brandenburg, and was better situated than he could be anywhere else for throwing succours into Silesia. The two armies kept a watchful eye on the motions of each other; and as the principal aim of M. Daun was to cut off the king's communication with Silesia, and of the king to cut off M. Daun's communication with Bohemia, a battle seemed inevitable, though great danger seemed to await that party who should begin the attack.

44
Who is sur-
prised and
defeated at
Hochkir-
chen.

In this critical posture of affairs, the Austrian general formed a design of attacking the Prussian camp in the night. In what manner he came to surprise such a vigilant enemy, has never been accounted for; but that such a surprise was actually accomplished on the 14th of October, is certain. In the dead of the preceding night, the Austrian army began to march in three columns towards the camp of the king of Prussia: and though the night was exceedingly dark, and they had a considerable way to go, they all arrived at the same time, in safety, without being discovered, and without the least confusion; and at five in the morning began a regular and well-conducted attack. The Prussians were in a moment thrown into confusion; Marshal Keith, one of their best generals, received two musket-balls, and fell dead on the spot. Prince Francis of Brunswick had his head shot off by a cannon-ball as he was mounting his horse; and every thing seemed to announce the total destruction of the army. Still, however, the king preserved his wonderful presence of mind, which indeed he never appears to have lost on any occasion. He ordered some detachments from his left to support his right wing; but the moment that these orders were received, the left itself was furiously attacked. General Ketzow, who commanded in that quarter, repulsed the Austrians with difficulty, and was not able to afford any considerable assistance to the right; which alone was obliged to sustain the weight of the grand attack. The Austrians, in the beginning of the engagement, had driven the Prussians out of the village of Hochkirchen; and as the fate of the day depended on the possession of that post, the hottest dis-

pute was there. The Prussians made three bloody and unsuccessful attacks on the village; on the fourth they carried it; but the Austrians continually pouring in fresh troops, at last drove them out with prodigious slaughter on all sides. The king then ordered a retreat, which was conducted in good order, without being pursued; however, this bloody action cost him 7000 men, together with a great number of cannon. The Austrians computed their own loss at 5000.

His Prussian majesty, having thus happily escaped such imminent danger, took every possible measure to prevent the enemy from gaining any considerable advantage from his defeat. Perceiving that the only advantage they wished to derive from it was to cover the operations of their armies in Silesia, and that he had now nothing to fear on the side of Saxony, he largely reinforced his own army from that of Prince Henry, and hastened into Silesia, in order to raise the siege of Neiss, which had been completely invested on the 4th of October. On the 24th of that month, therefore, he quitted his camp, and, making a great compass, to avoid obstructions from the enemy, arrived in the plains of Gorlitz. A body of the Austrians had in vain attempted to secure this post before him, and some who arrived after him were defeated with the loss of 800 men. From this place the king pursued his march with the utmost diligence; but was followed by general Laudohn, at the head of 24,000 men, who constantly hung on his rear, and harassed his army. The king, however, knowing the importance of his expedition, continued his march without interruption, and suffered his antagonist to obtain many little advantages without molestation. Daun, however, not content with the opposition given by Laudohn, sent a large body of horse and foot by another route to reinforce the generals Karfch and De Ville, who had formed the siege of Neiss and the blockade of Cosel, while he himself passed the Elbe, and advanced towards Dresden.

All these precautions, however, were of little avail. The generals Karfch and De Ville, notwithstanding their reinforcement, no sooner heard of the king of Prussia's approach, than they raised the siege of both places, and retired, leaving behind them a considerable quantity of military stores. The end of the Prussian monarch's march being thus accomplished, he instantly returned by the same way he came, and hastened to the relief of Saxony, the capital of which (Dresden) was in great danger from Marshal Daun. The place was but indifferently fortified, and garrisoned only by 12,000 men; so that it could not promise to hold out long against a numerous and well-appointed army. It was besides commanded by a large suburb, of which, if once the enemy got possession, all defence of the city must then be vain. For this reason M. Schmettau, the Prussian governor, determined to set these suburbs on fire, which was actually done November 10th, with an incredible loss to the inhabitants, as in the suburbs were carried on most of those valuable manufactures which render the city of Dresden remarkable. This disappointed the designs of M. Daun; but, though the action was agreeable to the laws of war, and had been executed with all the caution and humanity of which such an action was capable, yet the Austrians exclaimed against it as a piece of the most unprovoked and wanton cruelty recorded in history.

Saxony oppressed by the king of Prussia.

After the king of Prussia had approached Dresden, all the Austrian armies retired into Bohemia, where they took up their winter-quarters, as the king of Prussia did in Saxony. This unhappy country he said he would now consider as his own by right of conquest. But instead of treating the conquered people as his lawful subjects, he oppressed them in all possible ways, by levying the most severe and exorbitant contributions, surrounding the exchange with soldiers, and confining the merchants in narrow lodgings on straw-beds, till they drew upon their correspondents for such sums as he wanted.

47
Bohemia invaded by Prince Henry.

In 1759, as early as the 23d of February, the Prussians commenced their military operations. General Weberfow marched with a body of troops into Poland, where he destroyed several very large magazines belonging to the Russians, and returned into Silesia without any loss on the 18th of April. In the mean time, by some movements of the king of Prussia himself, the greatest part of the Austrian troops had been drawn towards the frontiers of Silesia. Prince Henry immediately took advantage of this opening, and on the 15th of April entered Bohemia with his army divided into two columns. One, commanded by himself, marched towards Peterswade; the other, under general Hulsen, passed by the towns of Pasberg and Commottau. That commanded by Prince Henry himself penetrated as far as Loboschutz and Leitmeritz; the enemy flying everywhere before them, and burning or abandoning the vast magazines which they had amassed in these parts. The body under general Hulsen had a more active employment. A strong pass at Pasberg was defended by a considerable body of Austrians. General Hulsen, having conducted his cavalry by another way in such a manner as to fall directly on their rear, attacked them in front with his infantry, drove them out of their intrenchments, and totally defeated them with the loss of a great number killed, and 2000 taken prisoners, while that of the Prussians did not exceed 70 in killed and wounded. After this exploit they returned into Saxony, with hostages for the contributions which they had largely exacted during the course of their expedition.

48
A body of Austrians defeated by General Hulsen.

Some other successes obtained by Prince Henry, cleared the country of Franconia of his enemies; but now the approach of the Russians seemed once more to bring the affairs of the king of Prussia to a crisis. Notwithstanding the destruction of their magazines, they had continued to advance into Silesia, where they were opposed by Count Dohna; but as the troops he had with him were very far inferior to his enemies, he found it impossible to do more, at least with any appearance of success, than to observe their motions and harass them on their march. But this was so displeasing to the king, that he disgraced this general, and appointed Wedel to succeed him, with orders to attack the Russians at all events. To enable him, however, in some measure to comply with this desperate order, he sent him some reinforcements, which brought his army up to near 30,000. With these, on the 23d of July 1759, General Wedel attacked 70,000 Russians posted in the most advantageous manner at Zulichau, and defended by a numerous artillery. Though the Prussians marched on to certain destruction and disgrace, they sustained the attack for a long time with

unparalleled resolution. At last, however, they gave way, and were obliged to retire with the loss of 4700 killed or taken prisoners, and 3000 wounded.

The consequences of this victory were, that the Russians penetrated into the king's territories, and took possession of the towns of Crossen and Frankfort on the Oder, which made it absolutely necessary for the king to come in person to oppose them. Accordingly, on the 4th of August, he joined Wedel with a considerable body of forces, having left the greatest part of his army in Saxony under Prince Henry. But as Marshal Daun had sent a body of 12,000 horse and 8000 foot under General Laudohn to the assistance of the Russians, the king still found himself unable to fight them; as, with this and some other reinforcements, their army now amounted to upwards of 90,000. He therefore recalled General Finck, whom he had sent into Saxony with 9000 men; but, with all his reinforcements, it was found impossible to augment his army to 50,000 complete. His situation, however, was now so critical, that a battle was unavoidable; and therefore, on the 12th of August, with this inferiority of number, the king attacked his enemies strongly intrenched, and defended by a prodigious number of cannon. In this action, his principal effort was against the left wing of the Russian army. He began the attack, according to custom, with a heavy cannonade; which having produced the desired effect, he attacked that wing with several battalions disposed in columns. The Russian intrenchments were forced with great slaughter, and 72 pieces of cannon were taken. But still there was a defile to be passed, and several redoubts which covered the village of Cunnerdorf to be mastered. These were attacked with the same resolution, and taken one after another. The enemy made another stand at the village, and endeavoured to preserve their ground there by pushing forward several battalions of horse and foot: but this also proved unsuccessful; they were driven from post to post quite to the last redoubts. For upwards of six hours the Prussians were successful, and everywhere broke the enemy with prodigious slaughter; drove them from almost all the ground they had occupied before the battle, took more than half their artillery, and scarce any thing seemed wanting to make the victory complete. In these circumstances, the king wrote the following billet to the queen: "Madam, we have beat the Russians from their intrenchments. In two hours expect to hear of a glorious victory." Of this victory, however, he deprived himself, by an excessive eagerness for conquest. The enemy, defeated almost in every quarter, found their left wing, shattered as it was, to be more entire than any other part of their army. Count Soltikoff, the Russian general, therefore assembled the remains of his right wing, and, gathering as many as he could from his centre, reinforced the left, and made a stand at a redoubt which had been erected on an advantageous eminence in a place called *the Jews burying-ground*. All the king's generals are said to have been of opinion, that he ought to allow the Russians the peaceable possession of this post. Their army had already suffered so much, that it would have been impossible for them to have attempted any enterprise of consequence after the battle; but their artillery was still numerous, the post very strong, and the Prussian troops greatly fatigued. These reasons for a few mo-

ments had some weight with the king: but the natural impetuosity of his temper getting the better of his reason, he led on his wearied troops again and again; till at last, when their strength was in a manner totally exhausted, they were attacked and utterly routed by the Austrian and Russian cavalry, the former of which had hitherto remained quite inactive, and were therefore quite fresh, and irresistible by the enfeebled Prussians. The night, and the prudent use of some eminences, prevented the total destruction of the army; however, their loss amounted to 20,000 men killed and wounded. The king, when he found the victory totally lost, sent another billet to the queen, expressed in the following manner: "Remove from Berlin with the royal family; let the archives be carried to Potsdam; the town may make conditions with the enemy."

Immediately after this defeat, the king set himself about repairing his losses with the utmost diligence. In a few days every thing was again put in order in his camp. He replaced his artillery from Berlin; recalled General Kliest with 5000 men from Pomerania; detached 6000 from his own army to the defence of Saxony; and with the remainder put himself between the Russians and Great Glogau, covering that city which had been the chief object of their designs; and in short, notwithstanding their victory, obliged them to return to Poland without accomplishing any thing besides the carnage at Cunnersdorf.

The misfortunes of the Prussian monarch, however, were not at an end. Prince Henry indeed, by a most extraordinary and well-conducted march, entered Saxony, which was now totally over-run by the armies of the enemy. At the same time, strong detachments having been sent into that country under generals, Finck and Wunsch, the whole was in a short time recovered except Dresden. Towards this place Marshal Daun retired, and in all probability would soon have been obliged to leave Saxony entirely. But the king's impatience could not be satisfied without cutting off his retreat, and forcing him to a battle; for which purpose he sent General Finck with upwards of 12,000 men according to the Prussian account, but 20,000 according to the Austrians, to seize some passes through which M. Daun could only take his route towards Bohemia. This commission was executed with great exactness; but the Prussian general, having probably advanced too far into these defiles, and neglected to preserve a communication with the main army, gave his enemy an opportunity of surrounding him, and at last forcing him and his whole army to surrender prisoners of war. This disaster was soon after followed by another. General Dürcke was posted at the right of the Elbe, opposite to Meissen; but on the approach of a large body of Austrians, they prepared to retreat over the river into a place where they hoped to be more secure. But having been obliged by an hard frost to withdraw their bridge of boats, a thaw supervened, when they attempted to lay a bridge of pontoons, so that they were again obliged to have recourse to their boats. In this situation, their rear-guard was attacked with great fury by the Austrians, and all the soldiers who composed it killed or taken. The loss of the Prussians on this occasion was computed at 3000 men.

The year 1760 showed the Prussian monarch in a more

dangerous situation than he had ever yet experienced. Indeed his affairs now seemed to be altogether desperate. His losses were not to be measured by the number of the killed or prisoners, but by armies destroyed or taken. Forty generals had died or been killed in his service since the beginning of October 1756, exclusive of those who were wounded or taken prisoners. This of itself would have been an irreparable loss, had not the very wars which destroyed these furnished others equally capable of filling their places. But another deficiency, which could not be remedied, still remained.—The king had, by his indefatigable industry and exertions, supplied all the deficiencies of men in his armies, but they were not the same men as before. The hardy veterans, with whom he had originally taken the field, were now no more, and their places were supplied by others who had neither the same experience nor discipline; so that now he was obliged to supply this deficiency by his own genius and heroism.

But whatever abilities the Prussian monarch might possess, and though he undoubtedly exerted them to the utmost, it seemed only to be contending against fate, and his enemies gained still greater and greater advantages. General Laudohn, with whom none but the king himself seems to have been able to cope, by a series of artful movements, drew into a disadvantageous situation M. Fouquet, one of the Prussian generals, with a strong body of forces. Perceiving it impossible for them to escape, Laudohn then made a violent attack on their intrenchments in the dead of the night of June 23d. The Prussians made a gallant defence, but at last were all killed or taken prisoners except about 300. Of the Prussians were killed 4000, and 7000 taken prisoners; 58 pieces of cannon, and a great number of colours, were also lost. The victory, however, was dear bought; for the Austrians lost above 12,000 men in killed and wounded; whom, however, they could better spare than the Prussians, on account of their numbers.—This action was called *the battle of Landshut*.

Baron Laudohn failed not to improve this victory to the utmost. He instantly turned back from Landshut, and fell upon the city of Glatz; which he took in a very short time, with the garrison who defended it, consisting of 2000 men. In this place were found 101 pieces of brass cannon, with immense quantities of provisions and military stores. From thence he marched against Breslau, and immediately invested it. But, in the mean time, the king of Prussia, whose motions had been all this time counteracted by M. Daun in Saxony, marched with his usual rapidity towards Silesia. By this means he drew M. Daun out of Saxony; and indeed the Austrian general used such expedition, that he gained two full days on the king. This was no sooner known to his Prussian majesty, than he returned with the same expedition that he had advanced, and sat down before Dresden. Of this M. Daun soon received intelligence, and returned also. In the mean time, however, the buildings of the city were terribly shattered by the king's cannon and bombs which continually played on it. His endeavours, however, proved ineffectual to reduce it before the arrival of M. Daun. The siege had been begun on the 13th of July, and on the 19th M. Daun appeared within a league of Dresden. The

Prussians then redoubled their efforts. They had that day received reinforcements of heavy cannon and mortars, with which they battered the place incessantly. The cathedral church, New Square, several principal streets, and some palaces, and the noble manufactory of porcelain, were entirely destroyed. The siege was continued till the 22d: but, on the night of the 21st, M. Daun had thrown 16 battalions into the city; which rendered it impossible for the king to continue longer before it with any prospect of success. He therefore raised the siege, and retired without molestation, though there were three considerable armies of the enemy in the neighbourhood. Breslau was fiercely bombarded by Laudohn, but the approach of Prince Henry obliged him to desist from his enterprise on the 5th of August.

57

him.

But, in the mean time, the fortune of the king seemed likely to be terminated by one fatal stroke. Finding it impossible for him to carry on a defensive war, he marched towards Silesia with such astonishing rapidity, that before the middle of August he had advanced 200 miles, leaving Marshal Daun with his army far behind him. This expedition he undertook in order to engage General Laudohn before he could have time to effect a junction with Daun and Lacy, another Austrian general; which triple union seemed to threaten him with unavoidable destruction at once. This, however, he found it impossible to prevent: and the three armies, when joined, formed a most tremendous line of encampments, extending no less than 30 English miles; at the same time that every one of their posts was strong, and the communication between them easy. The king was strongly encamped at Lignitz; and for several days employed all his military skill in attempting to induce one of the bodies to detach itself from the rest, or to attack them at some disadvantage; but without effect. At last, the Austrian generals, having maturely weighed all circumstances, resolved to attack the king's camp itself, strong as it was; and Marshal Daun, remembering the advantage he had gained at Hochkirchen by an attack in the night-time, resolved to follow the same plan now. The plan therefore was laid in the following manner. The whole army, as soon as it should begin to grow dark, was to march from their several posts to such situations as were marked out for each corps: they were to strike their tents, but yet to keep up the fires in their camps, and to have the drums beat the tattoo as usual, by which means they had a probability of surprising the enemy; or if not, they judged it absolutely impossible for him to escape them, though he should be ever so much on his guard. In what manner the king of Prussia became acquainted with this plan, is not known. His friends attributed it to his own penetration and knowledge of the stratagems of war; the Austrians, to intelligence given him by deserters. But, in whatever way he became acquainted with this design, it is certain that he took the most effectual methods of preventing it. As the Austrian plan was to surround his camp, and this could not be done without the division of their army which he had so long desired, he resolved to intercept one of the parties; and if that should be disabled from acting, he could then more easily deal with the other two. Therefore, in the very evening calculated for

Prussia.

the decisive attack on his camp, he quitted it with the utmost privacy, and took an advantageous post on the road through which General Laudohn was to pass. The nature of this post was such, that at the same time that it stopped the progress of Laudohn in front, Daun would lie under great difficulties if he should attempt his rear; at the same time that, for his further security, the king strengthened the rear with several batteries. As soon as his army was drawn up, he divided it; leaving his right on the ground where it had been formed, to observe Marshal Daun, and to maintain that post; whilst with his left he turned in order to fall on the corps under General Laudohn. In the mean time, that commander, ignorant of the fate which was awaiting him, advanced with the utmost expedition towards the place which had been assigned him, in order to share in the glory of destroying the Prussian monarch; when, at three in the morning, on the 15th of August, a thick fog which covered the ground, suddenly clearing up, discovered, like the opening of a great scene, the dreadful front of the Prussian army regularly embattled, and advantageously posted. Laudohn, though surprised, made the best dispositions that circumstances would admit of, and an obstinate engagement ensued; in which however, he was at last obliged to yield to the superior skill of his adversary, with the loss of 10,000 killed, wounded, and prisoners, 82 pieces of cannon, and 23 pair of colours.

58

The victory, though complete, gave but a partial relief to the king of Prussia. The most essential service it did was the preventing of the Russians from joining these enemies which he already had. Count Czernichew had been advancing with 24,000 men, and had even passed the Oder; but was so intimidated by this news, that he instantly repassed that river on the same bridges which he had lately built, even though M. Daun sent him a strong body of troops in order to encourage him to advance. Soon after this battle, the king joined his brother Prince Henry at New Marche; and marched against Daun, who had begun to form the blockade of Schweidnitz, fell upon a corps under General Beck, made two battalions of Croats prisoners, and dispersed the rest, which obliged the enemy to abandon the enterprise they had just undertaken. About the same time, General Hulsén gained a considerable advantage over the Imperial army in Saxony, with very trifling loss on his part, by which he effectually prevented them from cutting off his communication with the city of Torgau.

By these successes the affairs of his Prussian majesty seemed to revive: but there was no end of his enemies. The late manœuvres had drawn him so far into Silesia, that his communication with Brandenburg was almost wholly cut off. The Russian army, which after it had repassed the Oder began to move out of Silesia, sent forward a powerful detachment under Count Czernichew towards the march of Brandenburg. A body of 15,000 Austrians, under the generals Lacy and Brentano, and the whole united body of Austrians and Imperialists which acted in Saxony, began their march in concert with the Russians, and proposed to unite at the gates of Berlin. These armies amounted to 40,000 men. To oppose this formidable power, general Hulsén called to his assistance general Werner, who had been sent with a body of troops into Pome-

rania;

Prussia.

59
Berlin taken by the Austrians and Russians.

rania; but, after being joined by him, their united forces were found not to exceed 15,000 or 16,000 men. To attempt a defence of the capital with this force would have been little short of madness: and therefore these commanders were obliged to leave Berlin to its fate; which indeed, considering the barbarity of the Russians and the animosity of the Austrians, seemed to be a dreadful one. However, by the powerful mediation of several foreign ministers, the town obtained terms which were not altogether intolerable; but the magazines, arsenals, and foundries were destroyed, and an immense quantity of military stores seized with a number of cannon and other arms. The city was first obliged to pay 800,000 guilders, after which a contribution of 1,900,000 crowns was laid on: yet, notwithstanding this, many violences were committed, and the king's palace was plundered and the furniture abused in a scandalous manner.

60
Extreme embarrassment of the king.

The combined armies staid in Berlin only four days; dreading the severe vengeance of the king of Prussia, who they heard was advancing towards that place with great expedition. But so great were the embarrassments which now attended that monarch, that it seemed absolutely beyond human power to retrieve his affairs. The Imperialists, on their return from Berlin, having no army to oppose them, made themselves masters of Leipzig, Torgau, Meissen, and Wirtemberg; in which last city they found the grand magazine of the Prussians immensely stored with provisions, ammunition, &c. M. Stainville also, with a detachment from Broglie the French general's army, laid the city and duchy of Halberstadt under contribution. In Eastern Pomerania, the Russians had besieged Colberg by sea and land. In the Western Pomerania, the Swedes advanced with great celerity, hoping to share in the plunder of Berlin. In Silesia, the king no sooner began his march to the northward, than Laudohn advanced, and laid siege to the important fortrefs of Cosel; and, to complete this distress and embarrassment, the king himself was attended at every step by Count Daun with a superior army well prepared to take every advantage.

In this desperate situation the king, being joined by his generals Hulsen and prince Eugene of Wittemberg with the corps under their command, advanced up the Elbe, while M. Daun fell back to cover Leipzig and Torgau: but the latter, finding that the Prussians directed their march towards the Elbe, encamped within reach of Torgau; one part of his army extending to the Elbe, by which he was covered on that side, whilst on the other he was covered by hills and woods, so that it was impossible to choose a more advantageous situation. The Prussian army did not amount to 50,000 men, whilst that of the Austrians exceeded 86,000: yet such were the unfortunate circumstances of the king, that he was obliged to fight under all these disadvantages; and therefore he caused his army to be informed, that he was now to lead them to a most desperate attempt, that his affairs required it, and that he was determined to conquer or die. His soldiers unanimously declared that they would die with him.

61
He defeats Count Daun at Torgau.

The 3d of November 1760 was the day on which this important affair was decided. The king divided his forces into three columns. General Hulsen was to take post with one in a wood that lay on the left of the Austrian army, and had orders not to move until he

found the rest of the Prussians engaged. General Ziethen was to charge on the right; and the great attack in front was to be conducted by the king in person. His forces were disposed in such a manner, that either his right or left must take the enemy in rear and close them in, so as to disable them from undertaking any thing against the part where he intended to effect his principal attack. On the other hand, M. Daun perceiving the king to be serious in his design of fighting, to prevent confusion, sent all his baggage over the Elbe, across which he threw three bridges in case a retreat should be necessary. At the same time he caused Torgau to be evacuated; and then, extending his first line to a village called Zinne on the left, he stretched it to another called Crostwitz on the right; supporting the right of his second line upon the Elbe. In this disposition he was found, when, about two o'clock in the afternoon, the king began his attack. He was received by the fire of 200 pieces of cannon, which were disposed along the Austrian front. The Prussians were thrice led on to the attack; but were every time repulsed and broken with terrible slaughter. The king at length commanded a fresh body of cavalry to advance, which at first compelled the Austrians to retire; but new reinforcements continually coming in, this cavalry was in its turn obliged to fall back, and the Prussians maintained themselves with extreme difficulty, until General Ziethen, with the right wing, attacked the enemy in the rear, repulsed them, and possessed himself of some eminences which commanded the whole Austrian army. Encouraged by this success, the Prussian infantry once more advanced, mastered several of the enemy's intrenchments, and made way for a new attack of their cavalry, which broke in with irresistible fury on the Austrians, and threw several bodies of them into irreparable disorder. It was now about 9 o'clock, and of consequence both armies were involved in thick darkness; yet the fire continued without intermission, and the battalions with a blind rage discharged at one another without distinguishing friend from foe. M. Daun received a dangerous wound in the thigh, and was carried from the field, which probably hastened the defeat of his troops. The command then devolved on Count O'Donnell; who, finding the greatest part of his troops in disorder, the night advanced, and the enemy possessed of some eminences which commanded his camp, and from which it was in vain to think of driving them, ordered a retreat, which was conducted with wonderful order and exactness; none were lost in passing the bridges, and by far the greater part of their artillery was preserved. The loss of the Prussians was estimated at 10,000 killed and wounded, and 3000 taken prisoners. That of the Austrians in killed and wounded is not known; but 8000 were taken prisoners, with 216 officers, among whom were four generals.

The consequence of the victory of Torgau was, that the king recovered all Saxony except Dresden; and in the mean time General Werner having marched into Pomerania, the Russians raised the siege of Colberg, and retired into Poland, without having effected any thing further than wasting the open country. Werner then flew to the assistance of Western Pomerania, where he defeated a body of Swedes, and at last drove them totally out of the country. General Laudohn too abruptly raised the blockade of Cosel; and afterwards, abandoning

62

All Sax-
Dresden
recovered.

Prussia.

Prussia. abandoning Landshut, he retired into the Austrian Silesia, leaving the Prussian part entirely in quiet. M. Daun placed one part of his army in Dresden, and the other in some strong posts which lie to the south and west of it, by which he commanded the Elbe, and preserved his communication with Bohemia. The army of the empire retired into Franconia, and placed its headquarters at Bamberg.

Though these successes had, to appearance, retrieved the king's affairs in some measure, yet his strength seemed now to be wholly exhausted; and in the campaign of 1761, he made no such vigorous efforts as he had formerly done. The Russians, dividing themselves into two bodies, invaded Silesia and Pomerania. In the former country they laid siege to Breslau, and in the latter to Colberg. Tottleben also, who had commanded the Russian armies, was now removed on a suspicion that he had corresponded with the king of Prussia, and general Romanzow put in his place; by which it was expected that the Russian operations would be more brisk this year than formerly.

The king continued strongly encamped near Schweidnitz; where he was so closely watched by generals Daun and Laudohn, that he could attempt nothing. However, he defeated the designs of the Russians against Breslau, by sending general Platen to destroy their magazines; which he accomplished with great success, at the same time cutting off a body of 4000 of their troops. But this only brought the more sure destruction upon Colberg; to which place the body of Russians immediately marched, cruelly wasting the country as they went along. The king of Prussia could do nothing but send detachments of small parties, which, though they could not oppose their enemies in the field, yet he hoped, by cutting off the convoys of the enemy, might distress them to such a degree as to oblige them to abandon the siege, or at least protract it till the severity of the winter should render it impossible for them to carry on their operations. Thus he weakened his own army so much, that it was found requisite to draw 4000 men out of Schweidnitz in order to reinforce it; and no sooner was this done, than general Laudohn suddenly attacked and took that fortress by a coup de main. Colberg made a brave defence; but the troops sent to its relief being totally unable to cope with the Russian army consisting of 50,000 men, it was obliged to surrender on the 3d of December; and thus the fate of the Prussian monarch seemed to be decided, and almost every part of his dominions lay open to the invaders.

63 Schweidnitz and Colberg retaken.
64 Empress of Russia dies.
In the midst of these gloomy appearances the empress of Russia, the king's most inveterate and inflexible enemy, died on the 2d of January 1762. Her successor, Peter III. instead of being the king's enemy, was his most sanguine friend. As early as the 23d of February, in a memorial delivered to the ministers of the allied courts, he declared, that, "in order to the establishment of peace, he was ready to sacrifice all the conquests made in this war by the arms of Russia, in hopes that the allied courts will on their parts equally prefer the restoration of peace and tranquillity, to the advantages which they might expect from the continuance of the war, but which they cannot obtain but by a continuance of the effusion of human blood."—This address was not so well relished by the allies: however, they were very willing to make peace, provided it was

for their own interest; but they recommended to his attention fidelity to treaties, which constitutes a no less valuable part of the royal character, than humanity and disinterestedness. This answer made no impression on the czar; a suspension of hostilities took place on the 16th of March, which was followed by a treaty of alliance on the 5th of May. In this treaty the czar stipulated nothing in favour of his former confederates; on the contrary, he agreed to join his troops to those of the king of Prussia, in order to act against them. Sweden, which had for a long time acted under the direction of Russian counsels, now followed the example of her mistress, and concluded a peace with Prussia on the 22d of May.

It is not to be supposed that the king of Prussia would remain long inactive after such an unexpected turn in his favour. His arms were now everywhere attended with success. Prince Henry drove the Imperialists from some important posts in Saxony, by which he secured all that part which the Prussians possessed; and though the Austrians frequently attempted to recover these posts, they were constantly repulsed with great slaughter. The king was not joined by his new allies till the latter end of June; after which he drove M. Daun before him to the extremity of Silesia, leaving the town of Schweidnitz entirely uncovered, and which the king immediately prepared to invest. In the mean time different detachments of Prussians, some on the side of Saxony, and others on that of Silesia, penetrated deep into Bohemia, laid many parts of the country under contribution, and spread an universal alarm. A considerable body of Russian irregulars also made an irruption into Bohemia, where they practised on the Austrians the same cruelties which they had long been accustomed to practise on the Prussians.

But while the king was thus making the best use of his time, he was all at once threatened with a fatal reverse of fortune by a new revolution in Russia. The emperor was deposed, and his deposition was soon after followed by his death. The empress, who succeeded him, suspected that her husband had been misled by the counsels of his Prussian majesty, against whom, therefore, she entertained a mortal enmity. She could not, however, in the very beginning of her reign, undertake again a war of so much importance as that which had been just concluded. She therefore declared her intention of observing the peace concluded by the late emperor; but, at the same time, of recalling her armies from Silesia, Prussia, and Pomerania; which indeed the unsettled state of the kingdom now made in some degree necessary. At the same time a discovery was made with regard to the king of Prussia himself, which turned the scale greatly in his favour. The Russian senate, flaming with resentment against this monarch, and against their late unfortunate sovereign; and the empress, full of suspicion that the conduct of the latter might have been influenced by the councils of the former, searched eagerly amongst the papers of the late emperor for an elucidation or proofs of this point. They found indeed many letters from the Prussian monarch; but in a strain absolutely different from what they had expected. The king had, as far as prudence would permit, kept a reserve and distance with regard to the too rash advances of this unhappy ally; and, in particular, counselled him to undertake nothing against

Prussia.

65 Peace between Russia, Sweden, and Prussia.

67 A new revolution in Russia.

the

Prussia.

the empress his consort. The hearing of these letters read is said to have had such an effect upon the empress, that she burst into tears, and expressed her gratitude towards the Prussian monarch in the warmest terms. Still, however, the Russian army was ordered to separate from the Prussians; but all the important places which the former had taken during the whole war were faithfully restored.

The king, finding that the Russians were no more to take an active part in his favour, resolved to profit by their appearance in his camp; and therefore, the very day after the order for their return had arrived, he attacked the Austrian army, and drove their right wing from some eminences and villages where they were advantageously posted; by which means he entirely cut off their communication with Schweidnitz, so that nothing could be attempted for its relief. Prince Henry kept them in continual alarms for Bohemia; and a great part of their attention, and no small part of their forces, were engaged on that side. Marshal Daun, now finding himself rendered almost incapable of undertaking any thing, detached general Laudohn, with a force very much superior, to attack the prince of Bevern, and drive him from the advantageous post he occupied. But the prince defended himself with such resolution, that all the efforts of Laudohn could not succeed before the king had time to come to his assistance. The Austrians, being then put between two fires, were routed and pursued with terrible slaughter; after which, the king met with no more disturbance in his preparations for the siege, and the trenches were opened on the 18th of July. Marshal Daun made no attempts to relieve the place; but the garrison being very strong, it held out for near two months from the opening of the trenches. It is said that the attack was conducted, and the defence made, by two engineers who had written on the subject of the attack and defence of fortified places; and they were now practically engaged to prove the superiority of their systems. At last, however, the garrison, to the number of 8000 men, surrendered prisoners of war; and the whole body, except nine, were soon after drowned at the mouth of the Oder, on their passage to their intended confinement at Konigsberg.

The king of Prussia, now become master of Schweidnitz, turned his attention towards Saxony, where he considerably reinforced his brother's army, and made preparations for laying siege to Dresden. In this country the Austrians had lately met with some success, and driven Prince Henry back as far as Freyberg; but on the 29th of October, they were attacked by the Prussian army thus reinforced, and totally routed. Great numbers were slain, and near 6000 taken prisoners. This victory proved decisive: and the empress-queen, finding herself deserted by all her allies, was glad to conclude a treaty; the substance of which was, that a mutual restitution and oblivion should take place, and both parties sit down at the end of the war in the same situation in which they began it. This treaty is called the *peace of Hubertsburg*.

The war was no sooner concluded than the king of Prussia turned his attention to domestic policy, and the recovery of his dominions from those innumerable calamities which had befallen them during the war. He

immediately distributed lands to his disbanded soldiers, and gave them the horses of his artillery to assist them in their cultivation. By his wife and prudent management, the horrors of war were soon forgot; and the country was quickly in as flourishing a state as ever. Notwithstanding this pacific disposition, however, the king never slackened his endeavours for the defence of his country, by keeping a respectable army on foot; which might be able to act on the least emergency.

In the year 1778, a new difference with the house of Austria took place, concerning the duchy of Bavaria. But though the most enormous warlike preparations were made on both sides, and immense armies brought into the field, nothing of consequence was effected. What little advantage there was, seems to have been on the Prussian side, since they made themselves masters of several towns, and kept the war in the enemy's country. However, the emperor acted with so much caution and showed so much skill in a defensive war, that all the manœuvres of his Prussian majesty could gain no material advantage; as, on the other hand, his adversary was too wise to venture an engagement. A peace therefore was very soon concluded, and since that time the history of Prussia, during the remainder of the great Frederic's reign, affords no remarkable event which we have not mentioned in the life of that hero, and in the article *POLAND*. He left his crown to his nephew, whose character was not then much developed; and it was easily seen that a new kingdom, which had risen suddenly to such unexampled power and greatness as to excite the jealousy or apprehension of all its neighbours, would require great abilities to preserve it from dismemberment.

The late king had indeed bequeathed the most effectual securities to his successor for the preservation of his dominions, that human wisdom could provide or devise; by leaving him a full treasury, the finest army in the world, and a people enthusiastically attached to his memory and government. The new monarch, with these advantages, was not wanting to himself. The late king's predilection for the French language and French literature were not grateful to his subjects. The present sovereign began his reign with declaring in council, "Germans we are, and Germans I mean we shall continue;" giving directions at the same time, that their native language should resume its natural rank and station, from which for near half a century it had been degraded by the French. This was a very popular measure, and it was followed by another still more so. Observing that he had marked with great concern the progress of impiety and profaneness on the one hand, and of enthusiasm on the other, he declared, that he would not have his subjects corrupted either by fanatics or atheists, and strictly prohibited all publications tending to excite a contempt or indifference for religion.

Such, on his immediate accession to the throne, was the pacific conduct of the monarch, which endeared him to his subjects, and commanded the approbation of all good men. An opportunity soon occurred, in which he was thought to have displayed such talents in negotiation and in military arrangements, as proclaimed him in every respect a worthy successor of his uncle. The States of Holland, who had long been jealous of the power of the Stadtholder, and inclined to a republican government without any permanent chief, had gained

Prussia. ed such an ascendancy in the states general, that in 1786 and 1787 they in effect divested the prince of Orange of all his prerogatives (see *UNITED PROVINCES*.) They proceeded even to the seizure and imprisonment of the princess, sister to the king of Prussia; and depending upon support from France, treated with insolence every power connected with them in Europe. The court of Berlin did not witness these proceedings without indignation; and the king formed his plan for restoring the power of the Stadtholder with such secrecy and prudence, that perhaps nothing could surpass it but the bravery and military skill of the duke of Brunswick, by whom it was carried into execution. In the short space of one month, that accomplished general led 18,000 Prussians to Amsterdam, and restored the prerogatives of the prince of Orange. And here, we believe, the friends of the house of Brandenburg will agree with us, that our history of Prussia should conclude. The monarch's subsequent conduct has not been such as the beginning of his reign gave reason to expect. Something of it will be seen under the article *POLAND*, and more under *REVOLUTION* and *UNITED PROVINCES*; and it is not a subject upon which we delight to dwell.

74
Air, soil,
and population,
of
Prussia.

The air of Prussia is wholesome, and the soil fruitful in grain; affording, besides, plenty of pitcoal and other fuel. The rivers and lakes are well stored with fish; and amber is found on its coast towards the Baltic. The principal rivers are the Vistula, Bregel, Memel, the Passarge, and the Elbe; all of which frequently do damage by their inundations.

The inhabitants of this country were, by Dr Bussching, computed at 635,998 persons capable of bearing arms; and by another German author, at 450,000. Since the year 1719 it is computed that about 34,000 colonists have removed hither from France, Switzerland, and Germany; of which number one half were Saltzburghers. These emigrants have built 400 small villages, 11 towns, 50 new churches, and founded 1000 village-schools. The manners of the people differ but little from those of the Germans. The established religions are those of Luther and Calvin, but chiefly the former; though almost all other sects are tolerated.

75
Commerce
and manu-
factures.

The late king of Prussia, by the assistance of an excellent police, brought the commerce and manufactures of this country to a very flourishing state, which during his life were daily improving. The manufactures of Prussia consist in glass, iron-work, paper, gunpowder, copper, and brass-mills; manufactures of cloth, camblet, linen, silk, gold and silver lace, stockings, and other articles. The inhabitants export variety of naval stores; amber, lint-seed and hemp-seed, oat-meal, fish, mead, tallow, and caviar; and it is said that 500 ships are loaded with those commodities every year, chiefly from Königsberg.

76
Constitu-
tion.

His Prussian majesty is absolute through all his dominions; but the late king was too wise to oppress his subjects, though he availed himself to the full of his power. How the present sovereign treats them we know not, as the whole of his conduct for some time past has related to the Polish and French revolutions. The government of this kingdom is by a regency of four chancellors of state, viz. 1. The great-master; 2. The great-burgave; 3. The great-chancellor; and, 4. The great-marshal. There are also some other coun-

cils, and 37 bailiwicks. The state consists, 1. Of counsellors of state; 2. Of deputies from the nobility; and, 3. From the commons. Besides these institutions, the late king erected a board for commerce and navigation.

Prussia
Prylinc.

His Prussian majesty, by means of the happy situation of his country, its inland navigation, and the excellent regulations of his predecessor, derives an amazing revenue from this country, which, about a century and a half ago, was the seat of boors and barbarism. It is said, that amber alone brings him in 26,000 dollars annually. His other revenues arise from his demesnes, his duties of customs and tolls, and the subsidies yearly granted by the several states; but the exact sum is not known, though we may conclude that it is very considerable, from the immense charges of the late war.

77
Revenues.

The military regulations introduced by the late king had a wonderfully quick operation in forming his troops and recruiting his armies. Every regiment has a particular district assigned it, where the young men proper for bearing arms are registered; and when occasion offers, they join their regiment, and being incorporated with veterans they soon become well disciplined troops. The Prussian army, in time of peace, consists of 175,000 of the best disciplined troops in the world; and during the last war, that force was augmented to 300,000 men.

78
Military
strength.

The royal arms of Prussia are argent, an eagle displayed sable, crowned, or, for Prussia: azure, the Imperial sceptre, or, for Courland: argent, an eagle displayed, gules, with semicircular wreaths, for the marquisate of Brandenburg; to these are added the respective arms of the several provinces subject to the Prussian crown.

79
Royal
arms, &c.

There are two orders of knighthood; the first, that of the Black Eagle, instituted by Frederic I. on the day of his coronation at Königsberg, with this motto, *Suum cuique*. The sovereign is always grand-master; and the number of knights, exclusive of the royal family, is limited to 30. Next to this is the order of Merit, instituted by his late majesty; the motto is, *Pour le merite*.

PRUSSIAN BLUE. See *CHEMISTRY-Index*, at *Colouring Matter* and *Prussian Blue*.

PRUSSIC ACID, according to M. Berthollet, is a Chemical combination of azot of hydrogen and carbon. It appears much less akin to acids than to ammoniac; it has, however, too many properties in common with other acids not to place it in the same class, the rather because our classifications are always in a degree arbitrary, and ought to be considered rather as useful methods, than as divisions formed by nature. When the Prussic acid is combined with alkali and oxyd of iron, it cannot be separated by any other acid, unless heat be employed, or it be exposed to light; and nevertheless, when it is disengaged by one of these means, it cannot separate iron, even from the weakest acid, unless it be by a double affinity. It appears that this property is connected with the elastic state, which is unfavourable to these combinations: it must have lost this state, in other words its specific heat must be diminished, in order that it may possess its affinities with metallic oxyds and alkalis. Nitrous gas, oxygenated muriatic acid, and sulphureous acid, present analogous phenomena.

PRYNNE (William), an English lawyer, much distinguished

Prynne
||
Pfalmanazar.

distinguished in the civil commotions under Charles I. was born at Swainwick in Somersetshire in 1600. His *Hyfrionastix*, written against stage-plays in 1632, containing some reflections that offended the court, he was sentenced by the star-chamber to pay a fine of 5000 l. to stand in the pillory, to lose his ears, and to perpetual imprisonment. During his confinement, he wrote several more books; particularly, in 1637, one entitled *Notes from Ipswich*, which reflecting severely on the bishops, he was again sentenced by the star-chamber to another fine of 5000 l. to lose the remainder of his ears in the pillory, to be branded on both cheeks with S. L. for seditious libeller, and to be perpetually imprisoned in Caernarvon castle. Nothing but cutting off his hands could have prevented Prynne from writing: he wrote still; and in 1640, being set at liberty by the house of commons, he entered London in a kind of triumph, was elected into parliament for Newport in Cornwall, and opposed the bishops with great vigour, being the chief manager of archbishop Laud's trial. In the long parliament he was zealous in the Presbyterian cause; but when the Independents gained the ascendancy, he opposed them warmly, and promoted an agreement with the king. When the army garbled the house and refused him entrance, he became a bitter enemy to them and their leader Cromwell, and attacked them with his pen so severely, that he was again imprisoned: but he pleaded the liberty of the subject so successfully, that he was enlarged, to write more controversial books. Being restored to his seat after Cromwell's death, with the other secluded members, he assisted in promoting the restoration, and was appointed keeper of the Tower records; a place excellently well calculated for him, and where he was very useful by the collections he published from them. He presented 40 volumes of his works, in folio and 4to, to Lincoln's-inn library, of which society he was a member; and, dying in 1669, was buried under the chapel.

PRYTANES, in Grecian antiquity, were the presidents of the senate, whose authority consisted chiefly in assembling the senate; which, for the most part, was done once every day.

The senate consisted of 500, 50 senators being elected out of each tribe: after which, lots were cast, to determine in what order the senators of each tribe should preside; which they did by turns, and during their presidency were called *prytanes*. However, all the 50 prytanes of the tribes did not govern at once, but one at a time, viz. for seven days; and after 35 days, another tribe came into play, and presided for other five weeks; and so of the rest.

PSALM, a divine song or hymn; but chiefly appropriated to the 150 Psalms of David, a canonical book of the Old Testament.

Most of the psalms have a particular title, signifying either the name of the author, the person who was to set it to music or sing it, the instrument that was to be used, or the subject and occasion of it. Some have imagined that David was the sole author of the Book of Psalms; but the titles of many of them prove the contrary, as psalm cx. which appears to have been written by Moses. Many of the psalms are inscribed with the names *Korah*, *Jadubun*, &c. from the persons who were to sing them.

PSALMANAZAR (George), the fictitious name

of a pretended Formosan, a person of learning and ingenuity. He was born in France, and educated in a free-school, and afterwards in a college of Jesuits, in an archiepiscopal city, the name of which, as likewise those of his birth-place and of his parents, are unknown. Upon leaving the college, he was recommended as a tutor to a young gentleman; but soon fell into a mean rambling life, that involved him in disappointments and misfortunes. His first pretence was that of being a sufferer for religion. He procured a certificate that he was of Irish extraction, that he left that country for the sake of the Catholic faith, and was going on a pilgrimage to Rome. Being unable to purchase a pilgrim's garb, and observing one in a chapel, dedicated to a miraculous saint, which had been set up as a monument of gratitude by some wandering pilgrim, he contrived to take both the staff and cloak away; and, being thus accoutred, begged his way in fluent Latin, accosting only clergymen or persons of figure; whom he found so generous and credulous, that, before he had gone 20 miles, he might easily have saved money, and put himself in a much better dress: but as soon as he had got what he thought was sufficient, he begged no more; but viewed every thing worth seeing, and then retired to some inn, where he spent his money as freely as he had obtained it. Having heard the Jesuits speak much of China and Japan, he started the wild scheme, when he was in Germany, of passing for a native of the island of Formosa; and what he wanted in knowledge, he supplied by a pregnant invention. He formed a new character and language on grammatical principles, which, like other oriental languages, he wrote from right to left with great readiness; and planned a new religion, and a division of the year into 20 months, with other novelties, to credit his pretensions. He was now a Japanese convert to Christianity, travelling for instruction, with an appearance more wretched than even that of common beggars. He then entered as a soldier in the Dutch service; but, still desirous of passing for a Japanese, he altered his plan to that of being an unconverted heathen; and at Sluys, brigadier Lauder, a Scots colonel, introduced him to the chaplain, who, with a view of recommending himself to the bishop of London, resolved to carry him over to England. At Rotterdam, some persons having put shrewd questions to him, that carried the air of doubt, he took one more whimsical step, which was to live upon raw flesh, roots, and herbs; which strange food he thought would remove all scruples. The bishop of London patronized him with credulous humanity; and Psalmanazar found a large circle of friends, who extolled him as a prodigy. Yet were there some who entertained a just opinion of him, particularly the Drs Dalley, Mead, and Woodward; but their endeavours to expose him as a cheat only made others think the better of him, especially as those gentlemen were esteemed no great admirers of revelation. But in this instance at least, easiness of belief was no great evidence of penetration. He was employed to translate the church-catechism into the Formosan language, which was examined, approved, and laid up as a valuable MS; and the author, after writing his well-known *History of Formosa*, was rewarded and sent to Oxford to study what he liked, while his patrons and opponents were learnedly disputing at London on the merits of his work. The learned members

Pfalmanazar.

Psalmist
Platyrans.

members of the university were no better agreed in their opinions than those at London; but at length the sceptics triumphed. Some absurdities were discovered in his history, of such a nature as to discredit the whole narration, and saved him the trouble of an open declaration of his imposture; which however he owned at length to his private friends. For the remainder of his life, his learning and ingenuity enabled him to procure a comfortable support by his pen; he being concerned in several works of credit, particularly *The Universal History*. He lived irreproachably for many years, and died in 1763.

PSALMIST, in the church of Rome, one of the lesser ecclesiastical orders; the same with what among us is called *clerk, precentor, or singer*.

PSALMODY, the art or act of singing psalms. See **PSALM**.

Psalmody was always esteemed a considerable part of devotion, and usually performed in the standing posture: and as to the manner of pronunciation, the plain song was sometimes used, being a gentle inflection of the voice, not much different from reading, like the chant in cathedrals; at other times more artificial compositions were used, like our anthems.

As to the persons concerned in singing, sometimes a single person sung alone; sometimes the whole assembly joined together, which was the most ancient and general practice. At other times, the psalms were sung alternately, the congregation dividing themselves into two parts, and singing verse about, in their turns. There was also a fourth way of singing, pretty common in the fourth century, which was, when a single person began the verse, and the people joined with him in the close: this was often used for variety, in the same service with alternate psalmody.

The use of musical instruments, in the singing of psalms, seems to be as ancient as psalmody itself; the first psalm we read of being sung to the timbrel, viz. that of Moses and Miriam, after the deliverance of the Israelites from Egypt: and afterwards, musical instruments were in constant use in the temple of Jerusalem. See **ORGAN**.

PSALTER, the same with the book of psalms. See the article **PSALM**.

Among the religious in the Popish countries, the term *psalter* is also given to a large chaplet or rosary, consisting of 150 beads, according to the number of psalms in the psalter.

PSALTERY, a musical instrument, much in use among the ancient Hebrews, who called it *nebel*.

We know little or nothing of the precise form of the ancient psaltery. That now in use is a flat instrument, in form of a trapezium or triangle truncated at top: it is strung with 13 wire-chords, set to unison or octave, and mounted on two bridges, on the two sides: it is struck with a plectrum, or little iron rod, and sometimes with a crooked stick. Its chest or body resembles that of a spinet. See **NABLUM** and Plate CCCXLIV.

PSAMMETICUS, or **PSAMMITICHUS**, a renowned conqueror, who, subduing 11 other petty kings of Egypt, became the founder of the kingdom of Egypt, about 670 B. C. He is memorable likewise for taking the city of Azot, after a siege of 29 years; and for discovering the sources of the river Nile. See **EGYPT**, n° 10.

PSATYRIANS, a sect of Arians, who, in the

council of Antioch, held in the year 360, maintained that the Son was not like the Father as the will; that he was taken from nothing, or made of nothing; and that in God, generation was not to be distinguished from creation.

PSELLUS (Michael), a learned Christian of the 11th century, was, by birth, a Constantinopolitan of consular rank, and flourished under the emperor Constantine Monomachus. His genius and industry raised him far above the level of his contemporaries; and the female historian Anna Comnena speaks of him as one who had been more indebted for his attainments to his own excellent talent than to the instructions of his preceptors; adding, that having made himself master of all the wisdom of the Greeks and the Chaldeans, he was justly esteemed the most learned man of the age. Thus furnished, he became the chief instructor of the Constantinopolitan youth. He was at the same time the companion and the preceptor of the emperor, who was so captivated by the studies and amusements in which Psellus engaged him, that, according to Zonaras, he neglected the concerns of the empire. The Byzantine historians complain, that the emperor, deluded by the head of the philosophers (the title with which Psellus was honoured), lost the world. Meeting, towards the close of his life, with some disappointment, Psellus retired into a monastery, and soon afterwards died; the time of his death is uncertain. His works, which have been much celebrated, are, Commentaries upon Aristotle's Logic and Physics; a Compendium of Questions and Answers; and an Explanation of the Chaldean Oracles. The two latter works prove him to have been conversant, not only with Grecian, but with Oriental, philosophy.

PSEUDO, from *ψευδος*, a Greek term used in the composition of many words, to denote *false* or *spurious*: as the pseudo-acacia, or bastard acacia; pseudo-fumaria, or bastard-fumitory; pseudo-ruta, or bastard-rue, &c.

We also say, a pseudo-apostle, or false apostle; a pseudo-prophet, or false prophet, &c.

PSEUDO-China. See **SMILAX**.

PSEUDO-Galena, or *Black Jack*. See **ZINC**, and **MINERALOGY**, p. 62.

PSEUDO-Tinea, in natural history, the name of a very remarkable species of insect described by M. Reaumur, approaching to the nature of the *tinea*, or *clothes-moth* while in the worm-state, but not making themselves coats of the substance of leaves, cloth, &c. though they form a sort of cases for their defence against a very terrible enemy.

These creatures are of the caterpillar kind, and have, in the manner of many of these insects, 16 legs. They feed on wax, and for food enter the bee-hives; where they boldly engage the bees, and are not to be prevented by them from feeding, though at the expence of their habitations and the cells of their reservoirs of honey: so that it is no uncommon thing for a swarm of bees to be forced to change their place of habitation, and make new combs elsewhere; leaving the old ones to this contemptible victor, whom they know not how to drive out or dispossess.

Virgil and Aristotle, and all the authors who have written on bees, have complained of this destructive animal. It never eats the honey, but feeds only on the wax; attacking principally those waxy cells where

Psalms.
Pseudo.

Enfield's
History of
Philosophy.

Pseudo. the female bee deposits her eggs for the future progeny.

The bees, who are a match for most other creatures by means of their stings, would easily destroy these weak creatures, were it not for the impervious armour they are covered with. They form themselves a coat of armour of a double matter. The first, which immediately covers the body, is of a kind of silk of their own spinning; and, the outer covering over this is of the bees-wax: this is laid considerably thick; and the creature, just thrusting out its head to feed, goes on devouring the cells undisturbed, while a whole army of the inhabitants are in vain buzzing about him, and attempting to pierce him with their stings. He never forsakes his covering, but lengthens and enlarges it as he goes; and gnawing down the sides of the cells in his march, without staying to eat them one by one, the havoc and destruction he occasions are scarce to be conceived. When the time of the change of this creature approaches, it contracts its body within its double covering, and there changes into the nymph state; whence, after a proper time, it comes forth in form of a moth, with granulated horns and a crooked proboscis.

The bees have cunning enough to know their destructive enemy in this new form; and as this is a weak and defenceless state, they attack and destroy all the moths of this species they can meet with. They seldom are so fortunate, however, as to kill the whole race as soon as produced; and if only one escapes, it is able to lay a foundation of revenge for the death of its brethren. All the flies of the moth kind lay a vast number of eggs, and this is behind hand with none of them in that particular: the young ones produced from the eggs of one surviving female of this species are sufficient to destroy many honey-combs; nay, many hives of them. The moth produced by this caterpillar flies but little; yet it is very nimble in avoiding danger, by running, which it does with great swiftness.

There is a species of these pseudo-tineæ, or wax-eating caterpillars, which infest the subterraneous hives of wasps and other creatures which make wax: the manner of living, feeding, and defending themselves from their enemies, is the same in all the species. These last, if they are at any time distressed for food, will eat their own dung; the wax having passed almost unaltered through their bodies, and being still wax, and capable of affording them more nourishment on a second digestion. These species, though they naturally live on this soft food, yet if by any accident they meet with harder only, they know how to live upon it; and can eat a way into the covers and leaves of books, and make themselves cases and coverings of the fragments of these substances. The accurate author† of these observations describes also a kind of *pseudo-tinea* which feeds on wool, and another that eats leather; both making themselves houses also of the materials they feed on.

There is also another kind very destructive to corn: these make themselves a covering by fastening together a great number of the grains, and there living and eating in secret. All these creatures, whatever be their food or habitation, finally become *phalena*, or moths; and may be distinguished, even in this state, from the other species, by having granulated horns of a remarkable structure, and all of them a proboscis, or trunk, more or less incurvated.

PSEUDONYMUS, among critics, an author who publishes a book under a false or feigned name; as *cryptonymus* is given to him who publishes one under a disguised name, and *anonymus* to him who publishes without any name at all.

PSIDIUM, the GUAVA: A genus of the monogynia order, belonging to the icofandria class of plants; and in the natural method ranking under the 19th order, *Hesperideæ*. The calyx is quinquefid, superior; there are five petals; the berry is unilocular and monospermous. There are two species: 1. The pyriferum, or white guava; 2. The pomiferum, or red guava. Both these are thought to be only varieties of the same plant. The red guava rises to the height of 20 feet, and is covered with a smooth bark; the branches are angular, covered with oval leaves, having a strong midrib, and many veins running towards the sides, of a light green colour, standing opposite upon very short footstalks. From the wings of the leaves the flowers come out upon footstalks an inch and an half long: they are composed of five large roundish concave petals, within which are a great number of stamina shorter than the petals, and tipped with pale yellow tops. After the flower is past, the germen becomes a large oval fruit shaped like a pomegranate.

A decoction of the roots of guava is employed with success in dysenteries: a bath of a decoction of the leaves is said to cure the itch and other cutaneous eruptions. Guayava, or guava, is distinguished from the colour of the pulp, into the two species abovementioned, the white and the red; and, from the figure of the fruit, into the round, and the pear-fashioned or perfumed guava. The latter has a thicker rind, and a more delicate taste than the other. The fruit is about the bigness of a large tennis-ball; the rind or skin generally of a russet stained with red. The pulp within the thick rind is of an agreeable flavour, and interspersed with a number of small white seeds. The rind, when stewed, is eaten with milk, and preferred to any other stewed fruit. From the same part is made marmalade; and from the whole fruit is prepared the finest jelly in the world. The fruit is very astringent, and nearly of the same quality with the pomegranate; so should be avoided by all who are subject to costiveness. The seeds are so hard as not to be affected by the fermentation in the stomachs of animals; so that when voided with the excrements, they take root, germinate, and produce thriving trees. Whole meadows in the West Indies are covered with guavas, which have been propagated in this manner. The buds of guava, boiled with barley and liquorice, produce an excellent ptisan for diarrhœas, and even the bloody flux, when not too inveterate. The wood of the tree, employed as fuel, makes a lively, ardent, and lasting fire.

PSITTACUS, or PARROT, in ornithology; a genus belonging to the order of *pica*. The bill in this genus is hooked from the base; and the upper mandible is moveable: the nostrils are round, placed in the base of the bill, which in some species is furnished with a kind of cere: the tongue is broad, and blunt at one end: the head is large, and the crown flat: the legs are short, the toes placed two before and two behind. It might seem a wonder why nature has destined to this, which is not naturally a bird of prey, but feeds on fruits and vegetable substances, the crooked beak

allotted;

† Resum-
mur's His-
tory of
Insects.

Pittacus.

allotted to the hawk and other carnivorous birds : but the reason seems to be, that the parrot being a heavy bird, and its legs not very fit for service, it climbs up and down trees by the help of this sharp and hooked bill, with which it lays hold of any thing and secures itself before it stirs a foot ; and besides this, it helps itself forward very much, by pulling its body on with this hold.

Of all animals, the parrot and crocodile are the only ones which move the upper jaw ; all creatures else moving the lower only. As some particular animals beside are fond of particular foods, so the parrot loves nothing so much as the seeds of the carthamas, or bastard saffron ; and eats them without any hurt, though they are a purge when given to other creatures.

Parrots are found almost every-where within the tropics ; and in their natural state they live on fruits and seeds, though, when tame, they will eat flesh, and even fish.

In the East and West Indies they are very common, and in such warm climates are very brisk and lively ; here, however, they lose much of their vigour. They seldom make nests, but breed like owls in hollow trees ; they lay two eggs. At particular times they fly in very large troops, but still they keep two and two together. This genus consists of infinite variety, not so much owing to mixture of species, however, as might be supposed. They seem to run vastly into one another, so as to appear to be related, though received from different parts of the world ; this, however, may possibly be occasioned by their being carried from one place to another for the sake of sale. This uncertainty of native place has prevented Mr Latham from following Buffon's plan, and ranging them according to the places they are supposed to inhabit ; he divides them therefore into those with *uneven* and those with *even* tails.

Buffon ranges the parrots in two great classes : the first of which comprehends those of the Old Continent, and the second those of the New. The former he subdivides into five families, the Cockatoos, the Parrots, properly so called, the Lories, the long-tailed Paroquets, and the short-tailed ones ; and the latter into six, viz. the Macaos, the Amazonians, the Creeks, the Popinjays, the long-tailed Paroquets, and the short-tailed ones.

Mr Latham has increased the genus from 47 to 163 ; and since the time he wrote his *Index* at least 20 more have been discovered. They are very generally divided into three kinds : 1. The larger, which are as big as a moderate fowl, called *macaos* and *cockatoos* ; these have very long tails. 2. The middle-sized ones, commonly called *parrots*, which have short tails, and are a little larger than a pigeon. And, 3. The small ones, which are called *paroquets*, and have long tails, and are not larger than a lark or blackbird.

1. The *pittacus macao*, or red and blue macao, is red, except the wing quills, which above are blue, below rufous : the scapular feathers are variegated with blue and green : the cheeks are naked and wrinkled. It is about two feet seven inches and a half long, and about as big as a capon. Edwards says, when perfect, it will measure a full yard from bill to tail. It inhabits Brasil, Guiana, and other parts of South America. It was formerly very common in St Domingo, but is now rarely found there. It generally lives in moist woods, especially

such as are planted with a particular kind of palm, perhaps what is called the *macaw* tree. It does not in general learn to speak, and its voice is particularly rough and disagreeable. The flesh is hard, black, and unfavoury, but makes good soup, and is much used by the inhabitants of Cayenne and other places. This species, in common with other parrots, is subject to fits when tamed ; and though it will live for many years though the returns be pretty frequent, it generally falls a victim to that disease at last. The Americans call it *gonzalo*. 2. The *pittacus ararauna*, or blue and yellow macaw, is blue above, and yellow below, and the cheeks are naked, with feathery lines. It is about the same size with the last, and inhabits Jamaica, Guiana, Brasil, and Surinam. 3. The *pittacus severus*, or Brazilian green macaw, is black, with a greenish splendor ; the bill and eyes are reddish, and the legs are yellow. It is about one foot and five inches long, and is common in Jamaica, Guiana, and Brasil. It is however comparatively rare ; but it is extremely beautiful, and of a very amiable and sociable temper when familiar and acquainted ; but it can neither bear strangers nor rivals : its voice is not strong, nor does it articulate very distinctly the word *ara*. See Plate CCCCXVI.

4. The *pittacus aurora*, or yellow amazon, is about 12 inches long, of a green colour, with blue wing quills, and a white front ; its orbits are snowy. It inhabits Mexico or Brasil ; but in all probability the latter, from the one which Salerne saw, and which pronounced Portuguese words. The *pittacus guineensis*, or yellow lory, is about ten inches long, and is an inhabitant of Guinea. The bill is of a black colour ; the cere, the throat, and space about the eyes, are white ; above the eye there is a patch of yellow, and the rest of the head and neck is crimson. The breast is yellow, wing coverts green, and the quills are blue, edged with yellow. Under the wings, belly, thighs, vent, and to the under part of the tail, the colour is white, which last is tipped with red ; the legs are dusky, and the claws black. See Plate CCCCXVI.

5. The *pittacus pullarius*, red-headed Guinea parakeet, or Guinea sparrow, is about five inches and a half long. It inhabits Guinea, and is found in Ethiopia, the East Indies, and the island of Java, and sometimes in Surinam. It is green, with a red front, fulvous tail, black bar, and cinereous orbits. The male of this species is peculiarly affectionate to the female. See Plate CCCCXVI.

In Mr White's *Journal of a Voyage to New South Wales*, we find a description, with excellent engravings, of several species of this extensive genus ; and in Governor Philip's Voyage to the same place, we find descriptions and prints of several of the same species. But the most particular of the later authors are Buffon and Latham, especially the last ; to whose extensive and accurate work we therefore refer our readers for that information which our limits permit us not to give. See his *Synopsis*, vol. i. p. 194—323. See also Buffon, vol. vi. p. 63—245.

PSOAS, in anatomy. See there, *Table of the Muscles*.

PSOPHIA, in ornithology ; a genus belonging to the order *gallinae*. The bill is moderate ; the upper mandible is convex ; the nostrils are oblong, sunk, and pervious ; the tongue is cartilaginous, flat, and fringed.

Pittacus**Psophia.**

Pfophia,
Pforalea.

Plate
ccccxvi.

at the end; and the legs are naked a little above the knees. The toes are three before and one behind; the last of which is small, with a round protuberance beneath it, which is at a little distance from the ground. Mr Latham only enumerates two species: 1. *Pfophia crepitans*, or gold-breasted trumpeter. Its head and breast are smooth and shining green. By the Spaniards of Maynas it is called *trompetero*, and by the French at Cayenne *agami*, under which last Buffon describes it. It inhabits various parts of South America, Brazil, Guiana, Surinam, &c. but it is most plenty in the Amazon's country. It is about 20 inches long, being about the size of a large fowl, and lays eggs rather larger, of a blue green colour. It is met with in the Caribbee islands, where it is called a *pheasant*, and its flesh is reckoned as good as that of a pheasant. The most characteristic and remarkable property of these birds consists in the wonderful noise they make either of themselves, or when urged by the keepers of the *menagerie*. Some have supposed it to proceed from the anus, and some from the belly. It is now certain, however, that this noise proceeds from the lungs. See Buffon, vol. iv. p. 390, &c. Another very remarkable circumstance is, that they follow people through the streets, and out of town, and that too even perfect strangers. It is difficult to get rid of them; for if you enter a house they will wait your return, and again join you, though often after an interval of three hours. "I have sometimes (says M. de la Borde) betaken myself to my heels; but they ran faster, and always got before me; and when I stopped, they stopped also.—I know one (continues he) which invariably follows all the strangers who enter his master's house, accompanies them into the garden, takes as many turns as they do, and attends them back again. 2. *Pfophia undulata*, or undulated trumpeter, is about the size of a goose. The upper part of the body is of a pale reddish brown colour, beautifully undulated with black. The head is adorned with a dependent crest. On each side of the neck, beneath the ears, begins a list of black, widening as it descends, and meeting on the lower part before, where the feathers become greatly elongated, and hang loosely down. The under parts are generally white, the legs are of a dusky blue colour, like the bill. It is a native of Africa: Mr Latham's specimen came from Tripoli.

PSORALEA, in botany: A genus of the decandria order, belonging to the diadelphia class of plants; and in the natural method ranking under the 32d order, *Papilionacea*. The calyx is powdered, with callous points, and as long as the monospermous legumen. The most remarkable species are, 1. The primata or pinnated pforalea, rises with a woody soft stem, branching five or six feet high, pinnated leaves of three or four pair of narrow lobes terminated by an odd one, and at the axillas close-fitting blue flowers with white keels. It is a native of Ethiopia. 2. The bituminosa, or bituminous trifoliate pforalea, rises with a shrubby stalk, branching sparingly about two or three feet high, with ternate or three-lobed leaves of a bituminous scent, and blue flowers in close heads; it grows in Italy and in France. 3. The aculeata, or aculeated prickly pforalea, rises with a shrubby branching stem three or four feet high, with ternate leaves, having wedge-shaped lobes, terminating in a recurved sharp point,

and the branches terminated by roundish heads of blue flowers; it grows in Ethiopia. These plants flower here every summer; the first fort greatest part of that season, and the others in July and August; all of which are succeeded by seeds in autumn. Keep them in pots in order for removing into the green-house in winter. They are propagated by seeds, sown in a hot-bed in the spring; and when the plants are two or three inches high, prick them in separate small pots, and gradually harden them to the open air, so as to bear it fully by the end of May or beginning of June. They may also be propagated by cuttings any time in summer, planted in pots, and plunged in a little heat, or covered close with hand-glasses, shaded from the sun, and watered.

PSYCHOTRIA, in botany: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 47th order, *Stellata*. The calyx is quinque-dentate, persisting, and crowning the fruit; the corolla is tubulated; the berry globose; with two hemispherical falcated seeds.

The species are four, viz. 1. *Aspatica*; 2. *Serpens*; 3. *Herbacea*; and, 4. *Emetica*. They are all natives of Jamaica. See *IPECACUANHA*.

PSYLLI, (Strabo, Ptolemy): a people in the south of Cyrenaica, so called from king Psyllus, (Agathargides, quoted by Pliny): almost all overwhelmed by sand driven by a south wind (Herodotus). They had something in their bodies fatal to serpents, and their very smell proved a charm against them, according to Pliny, Lucan, &c.

Though we may justly look upon it as fabulous, that these people had any thing in their bodies different from others; it is, however, certain that there are in Egypt at this day some persons who have a method of handling the most poisonous serpents without any hurt. Of these Mr Hasselquist gives the following account:

"They take the most poisonous vipers with their bare hands, play with them, put them in their bosoms, and use a great many more tricks with them, as I have often seen. I have frequently seen them handle those that were three or four feet long, and of the most horrid sort. I enquired and examined whether they had cut out the vipers' poisonous teeth; but I have with my own eyes seen they do not. We may therefore conclude, that there are to this day Psylli in Egypt; but what art they use is not easily known. Some people are very superstitious, and the generality believe this to be done by some supernatural art which they obtain from invisible beings. I do not know whether their power is to be ascribed to good or evil; but I am persuaded that those who undertake it use many superstitions.

"The art of fascinating serpents is a secret amongst the Egyptians. It is worthy the endeavours of all naturalists, and the attention of every traveller, to learn something decisive as to this affair. How ancient this art is among the Africans, may be concluded from the ancient Marii and Psylli, who were from Africa, and daily showed proofs of it at Rome. It is very remarkable that this should be kept a secret for more than 2000 years, being known only to a few, when we have seen how many other secrets have within that time been re-

vealed

Psychotria,
Psylli.

Pŷylli.

vealed. The circumstances relating to the fascination of serpents in Egypt, related to me, were principally, 1. That the art is only known to certain families, who propagate it to their offspring. 2. The person who knows how to fascinate serpents, never meddles with other poisonous animals, such as scorpions, lizards, &c. There are different persons who know how to fascinate these animals; and they again never meddle with serpents. 3. Those that fascinate serpents, eat them both raw and boiled, and even make broth of them, which they eat very commonly amongst them; but in particular, they eat such a dish when they go out to catch them. I have been told, that serpents fried or boiled are frequently eat by the Arabians both in Egypt and Arabia, though they know not how to fascinate them, but catch them either alive or dead. 4. After they have eat their soup, they procure a blessing from their scheik (priest or lawyer), who uses some superstitious ceremonies, and amongst others, spits on them several times with certain gestures. This manner of getting a blessing from the priest is pure superstition, and certainly cannot in the least help to fascinate serpents; but they believe, or will at least persuade others, that the power of fascinating serpents depends upon this circumstance."

Notwithstanding this testimony of Hasselquid, the story of the incantation of serpents, though frequently alluded to in Scripture, has been generally treated as a fable. It is, however, affirmed as a certain truth, both by Mr Bruce and M. Savary. "There is no doubt (says the former of these travellers) of its reality. The Scriptures are full of it. All that have been in Egypt have seen as many different instances as they chose. Some have doubted that it was a trick; and that the animals thus handled had been first trained, and then deprived of their power of hurting; and fond of the discovery, they have rested themselves upon it, without experiment, in the face of all antiquity. But I will not hesitate to aver, that I have seen at Cairo (and this may be seen daily without any trouble or expence), a man who came from the catacombs, where the pits of the mummy birds are kept, who has taken a cerastes with his naked hand from a number of others lying at the bottom of a tub, has put it upon his bare head, covered it with the common red cap he wears, then taken it out, put it in his breast, and tied it about his neck like a necklace; after which it has been applied to a hen, and bit it, which died in a few minutes; and, to complete the experiment, the man has taken it by the neck, and beginning at his tail, has ate it as one would do a carrot or stock of celery, without any seeming repugnance.

"We know from history, that where any country has been remarkably infested with serpents, there the people have been screened by this secret.

"To leave ancient history, I can myself vouch, that all the black people in the kingdom of Sennaar, whether Funge or Nuba, are perfectly armed against the bite of either scorpion or viper. They take the cerastes in their hands at all times, put them in their bosoms, and throw them to one another as children do apples or balls, without having irritated them by this usage so much as to bite. The Arabs have not this secret naturally, but from their infancy they acquire an exemption from the mortal consequences attending the bite

of these animals, by chewing a certain root, and washing themselves (it is not anointing) with an infusion of certain plants in water."

From this account we should be apt to think, that these vipers really *would not* bite any who were thus armed against their poison; especially as he adds, that he "constantly observed, that the viper, however lively before, upon being seized by any of these barbarians, seemed as if taken with sickness and feebleness, frequently shut his eyes, and never turned his mouth towards the arm of the person who held him." Yet in another place, speaking of the activity of the cerastes, he says, "I saw one of them at Cairo, in the house of Julian and Rosa, crawl up the side of a box in which there were many, and there lie still, as if hiding himself, till one of the people who brought them to us came near him; and though in a very disadvantageous posture, sticking as it were perpendicularly to the side of the box, he leaped near the distance of three feet, and fastened between the man's forefinger and thumb so as to bring the blood. The fellow showed no signs of either pain or fear, and even kept him with us full four hours, without his applying any sort of remedy, or seeming inclined to do so."

It is difficult to see how these two accounts can be reconciled. If those who catch vipers are in danger of being bit by them *after* they are caught, certainly they must be so before, and then the whole relation becomes contradictory. Our author tells us, that these feats were performed *for a season*, by those who were artificially armed against the viper's poison, as well as those who had the exemption naturally; but though put in possession of the drugs, he never had the courage to make the experiment. That he should have made such a dreadful experiment on *himself*, no person in his senses would expect; but it is indeed very surprising, that he did not attempt by means of these medicines to arm some of the brute creatures, of the lives of which he was sufficiently prodigal, against the effects of that deadly poison by which so many of them perished.—As surprising it is, that he did not try what effect the root or its decoction would have upon the serpents themselves; or that though he says he had a small quantity of this extraordinary root by him, he gave neither drawing nor description of it.

Though it is impossible to reconcile the particulars of this account to one another, the general fact of the incantation is confirmed by the testimony of M. Savary. This writer tells us, that he saw at the feast of Sidi Ibrahim, a troop of people, seemingly possessed, with naked arms and a fierce look, holding in their hands enormous serpents, which twined round their body, and endeavoured to escape. These Pŷylli, grasping them strongly by the neck, avoided the bite; and notwithstanding their hissing, tore them with their teeth, and ate them alive, while the blood streamed from their mouth.

PTARMIGAN, in ornithology. See TERRAO.

PTELEA, SHRUB-TREFOIL: A genus of the monogynia order, belonging to the tetrandria class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is tetrapetalous; the calyx quadripartite inferior; the fruit is monospermous, with a roundish membrane in the middle.

Pŷylli
||
Ptelea.

The

Pteris.

The species are, 1. The trifoliata, or Carolina shrub-trefoil, hath a shrubby upright stem, dividing into a branchy head eight or ten feet high, covered with a smooth purplish bark, trifoliate leaves, formed of oval spear-shaped folioles, and the branches terminated by large bunches of greenish-white flowers, succeeded by roundish, bordered capfuls. 2. The viscosa, or viscous Indian ptelea, rises with several strong shrubby stems, branching erectly 12 or 15 feet high, having a light brown bark, spear-shaped, stiff, simple leaves, and the branches terminated by clusters of greenish flowers.

The first species is a hardy deciduous shrub, and a proper plant for the shrubbery and other ornamental plantations to increase the variety. It is propagated by seeds, layers, and cuttings.

The second species is a stove-plant, and is propagated commonly by seeds.

PTERIS, in botany; a genus of the order of filices, belonging to the cryptogamia class of plants. The fructifications are in lines under the margin. There are 19 species; the most remarkable is the aquilina, or common female fern. The root of this is viscid, nauseous, and bitterish; and like all the rest of the fern tribe, has a salt, mucilaginous taste. It creeps under the ground in some rich soils to the depth of five or six feet, and is very difficult to be destroyed. Frequent mowing in pasture-grounds, plentiful dunging in arable lands, but, above all, pouring urine upon it, are the most approved methods of killing it. It has, however, many good qualities to counterbalance the few bad ones. Fern cut while green, and left to rot upon the ground, is a good improver of land; for its ashes, if burnt, will yield the double quantity of salt that most other vegetables will.—Fern is also an excellent manure for potatoes; for if buried beneath their roots, it never fails to produce a good crop.—Its astringency is so great, that it is used in many places abroad in dressing and preparing kid and chamois leather.—In several places in the north, the inhabitants mow it green, and, burning it to ashes, make those ashes up into balls, with a little water, which they dry in the sun, and make use of them to wash their linen with instead of soap. In many of the Western Isles the people gain a very considerable profit from the sale of the ashes to soap and glass-makers.—In Glen Elg in Invernessshire, and other places, the people thatch their houses with the stalks of this fern, and fasten them down with ropes made either of birk-bark or heath. Sometimes they use the whole plant for the same purpose, but that does not make so durable a covering.—Swine are fond of the roots, especially if boiled in their wash.—In some parts of Normandy we read that the poor have been reduced to the miserable necessity of mixing them with their bread. And in Siberia, and some other northern countries, the inhabitants brew them in their ale, mixing one-third of the roots to two-thirds of malt.—The ancients used the root of this fern, and the whole plant, in decoctions and diet-drinks, in chronic disorders of all kinds, arising from obstructions of the viscera and the spleen. Some of the moderns have given it a high character in the same intentions, but it is rarely used in the present practice. The country people, however, still continue to retain some of its ancient uses; for they give the powder of it to destroy worms, and look upon a bed

of the green plant as a sovereign cure for the rickets in children.

PTEROCARPUS, in botany: A genus of the decandria order, belonging to the diadelphia class of plants; and in the natural method ranking under the 32d order, *Papilionaceæ*. The calyx is quinquevittate, the capsule falcated, filiceous, varicose. The seeds are few and solitary. There are four species, viz. 1. *Draco*; 2. *Ecastaphyllum*; 3. *Lunatus*; and, 4. *Santalinus*. This last is by some referred to the genus *Santalum*. It is called *red Saunders*; and the wood is brought from the East Indies in large billets, of a compact texture, a dull red, almost blackish colour on the outside, and a deep brighter red within. This wood has no manifest smell, and little or no taste. It has been commended as a mild astringent, and a corroborant of the nervous system: but these are qualities that belong only to the yellow sort.

The principal use of red Saunders is as a colouring drug; with which intention it is employed in some formulæ, particularly in the *tinctura lavendulæ composita*. It communicates a deep red to rectified spirit, but gives no tinge to aqueous liquors; a small quantity of the resin, extracted by means of spirit, tinges a large one of fresh spirit of an elegant blood-red. There is scarcely any oil, that of lavender excepted, to which it communicates its colour. Geoffroy and others take notice, that the Brazil woods are sometimes substituted for red Saunders; and the college of Brussels are in doubt whether all that is sold among them for Saunders be not really a wood of that kind. According to the account which they have given, their Saunders is certainly the Brazil wood; the distinguishing character of which is, that it imparts its colour to water.

PTEROCOCEUS, in botany, is a species of the genus *Calligonum*. See *CALLIGONUM*.

PTERONIA, in botany: A genus of the polygamia equalis order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is full of multipartite bristles; the pappus a little plumy; the calyx imbricated.

PTEROSPERMUM, in botany: A genus of the polyandria order, belonging to the monodelphia class of plants; and in the natural method ranking under the 37th order, *Columnifera*. The calyx is quinquepartite; the corolla consists of five oblong spreading petals. The filaments are about 15, which unite towards the base into a tube. The style is cylindrical; the capsule is oval, woody, and quinquelocular, each of which are bivalved, containing many oblong, compressed, and winged seeds. There is only one species, viz. the *Pentapeetes*, a native of the East Indies; the wood of which is very hard, and very like that of the holly-tree.

PTINUS, a genus of insects belonging to the order of coleoptera. The antennæ are filiform: The last or exterior articulations are longer than the others: The thorax is nearly round, without a margin, into which the head is drawn back or received: The feet are made for leaping. The most remarkable species are,

1. The *pectinicornis*. This is produced from a worm that lodges in wood and the trunks of trees, such as the willow, where it makes deep round holes, turns to a winged insect, takes flight, and roosts upon flowers. It is distinguished by its antennæ pectinated on one side

Pterocar-
pus
||
Ptinus.

Ptisan
||
Ptolemy.

side, whence it has the name of *feathered*. The elytra and thorax are of a deep clay-coloured brown, the antennæ and legs are of a pale brown.

2. The *pertinax*. The form of this insect resembles the preceding one, saving that its antennæ are filiform. It is all over of a deep blackish brown colour resembling foot. It attacks household furniture, cloathes, furs, and especially animals dried and preserved in collections of natural history, where it makes great havoc. When caught, this insect bends its legs, draws back its head, and lies as if it was dead till it thinks itself out of danger. It cannot be forced out of this state of inaction either by pricking or tearing: nothing but a strong degree of heat can oblige it to resume its motion and run away. There are many beautiful varieties of this genus; but they in general escape our attention by their minuteness, and living among hay, dried leaves, and divers other dusty matters, where they undergo their metamorphoses. The larvæ of some are found in trunks of decayed trees, in old tables, chairs, &c. See Plate CCCCXVI.

PTISAN, is properly barley decorticated, or deprived of its hulls, by beating in a mortar, as was the ancient practice; though the cooling potion obtained by boiling such barley in water, and afterwards sweetening the liquor with liquorice-root, is what at present goes by the name of *Ptisan*; and to render it laxative, some add a little fenna or other ingredient of the same intention.

PTOLEMAIC *System of Astronomy*, is that invented by Claudius Ptolemæus. See PTOLEMY (Claudius).

PTOLEMAIS, (anc. geog.); the port of Arsinoe, situated on the west branch of the Nile, which concurs to form the island called *Nomos Heracleotes*, to the south of the vertex of the Delta.

PTOLEMAIS (Strabo); the largest and most considerable town of the Thebais, or Higher Egypt, and in nothing short of Memphis; governed in the manner of a Greek republic; situated on the west side of the Nile, almost opposite to Coptos. This town, which was built by Ptolemy Philadelphus, is now known by the name of *Ptolometa*. The walls and gates are still entire, and there are a vast number of Greek inscriptions, but only a few columns of the portico remain. There is likewise an Ionic temple, done in the most ancient manner of executing that order, of which Mr Bruce took a drawing, which is preserved in the king's collection.—Another, of Cyrenaica, anciently called *Barce*.—A third of the Troglodytica, surnamed *Epitheras*, from the chase of wild beasts, as elephants: lying in the same parallel with Meroe (Strabo); on the Arabian gulf (Pliny); 4820 stadia to the south of Berenice.—A fourth, of Galilee, anciently called *Aca*, or *Acon*; made a Roman colony under the emperor Claudius (Pliny).—A fifth of Pamphylia; situated near the river Melas, on the borders of Cilicia Aspera.

PTOLEMY (Soter, or Lagus), king of Egypt, a renowned warrior, and an excellent prince: he established an academy at Alexandria, and was himself a man of letters. Died 284 B. C. aged 92.

PTOLEMY (Philadelphus), his second son, succeeded him to the exclusion of Ptolemy Ceraunus. He was renowned as a conqueror, but more revered for his great vir-

tues and political abilities. He established and augmented the famous Alexandrian library, which had been begun by his father. He greatly increased the commerce of Egypt, and granted considerable privileges to the Jews, from whom he obtained a copy of the Old Testament, which he caused to be translated into Greek, and deposited in his library. This is supposed to have been the version called the *Septuagint*. He died 246 years B. C. aged 64.

PTOLEMY (Ceraunus), the elder brother, fled to Seleucus king of Macedon, who received him hospitably; in return for which he assassinated him, and usurped his crown. He then invited Arsinoe, who was his widow and his own sister, to share the government with him; but as soon as he got her in his power, he murdered her and her children. He was at length defeated, killed, and torn limb from limb by the Gauls, 279 B. C.

PTOLEMY (Claudius), a celebrated mathematician and astrologer, was born at Pelusium, and surnamed by the Greeks *Most Divine* and *Most Wise*. He flourished at Alexandria in the second century, under the reigns of Adrian and Marcus Aurelius, about the 138th year before the Christian era. There are still extant his *Geography*, and several learned works on astronomy. The principal of which are, 1. *The Almagest*; 2. *De Judiciis Astrologicis*; 3. *Planisphærium*. His system of the world was for many years adopted by the philosophers and astronomers; but the learned have rejected it for the system of Copernicus. See ASTROMONY, n° 16.

PTYALISM, in medicine, a salivation, or frequent and copious discharge of saliva. The word is Greek, formed from πτυω "to spit."

PUBERTY, denotes the age at which a person is capable of procreating or begetting children. See MAN n° 13—18.

PUBERTY, in law, is fixed at the age of 12 in females, and 14 in males; after which they are reckoned to be fit for marriage. But as to crimes and punishments, the age of puberty is fixed at 14 in both sexes.

PUBES, in anatomy, denotes the middle part of the hypogastric region in men or women, lying between the two inguina or groins.

Section of the PUBES. See MIDWIFERY and SIGAULTIAN Operation.

PUBES, in botany, the hair or down on the leaves of some plants. See HAIR.

PUBLICAN, among the Romans, one who farmed the taxes and public revenues.

PUBLICATION, the art of making a thing known to the world, the same with promulgation.

PUBLIUS SYRUS, a Syrian mimic poet, who flourished about 44 years before Christ. He was originally a slave sold to a Roman patrician, called *Domitius*, who brought him up with great attention, and gave him his freedom when of age. He gained the esteem of the most powerful men at Rome, and reckoned J. Cæsar among his patrons. He soon eclipsed the poet Laberius, whose burlesque compositions were in general esteem. There remains of Publius, a collection of moral sentences, written in iambics, and placed in alphabetical order.

Ptolemy
||
Publius.

Puceron
Puffendorf.

OAK PUCERON, a name given by naturalists to a very remarkable species of animal of the puceron kind. They bury themselves in the clefts of the oak and some other trees, and getting into the crevices, where the bark is a little separated from the wood, they there live at ease, and feed to their fill, without being exposed to their common enemies. They are larger than the other pucerons, the winged ones being nearly as large as a common house fly; and those without wings are also larger than any other species of the same genus. The winged ones are black, and the others of a coffee colour. Their trunk is twice the length of their bodies, and, when walking, it is carried straight along the belly, trailing behind it with the point up. When the creature has a mind to suck a part of the tree that is just before it, it draws up, and shortens the trunk, till it brings it to a proper length and direction; but when it sucks in the common way, it crawls upon the inner surface of the bark, and the turned up end of the trunk, which resembles a tail, fixes itself against the wood that is behind it, or contiguous to its back, and sucks there. The extremity of this trunk holds so fast by the wood, that when it is pulled away, it frequently brings a small piece of the wood away with it.

The ants are as fond of these as of the other species of pucerons, and that for the same reason, not feeding upon them, but on their dung, which is a liquid matter of a sweet taste, and is the natural juice of the tree, very little altered. These creatures are the surest guides where to find this species of puceron; for if we at any time see a number of these crawling up an oak to a certain part, and there creeping into the clefts of the bark, we may be assured that in that place there are quantities of these oak pucerons. The ants are so extremely fond of the juices of the tree, when prepared for them by passing through the body of this animal, that when the puceron has a drop not yet evacuated, but hanging only in part out at the passage, an ant will often seize on it there.

PUCERONS, *Vine-fretters*, or *Plant-lice*. See **APHIS**.

PUDENDA, the parts of generation in both sexes. See **ANATOMY**, n° 107 and 108.

PUERILITY, in discourse, is defined by Longinus to be a thought which, by being too far fetched, becomes flat and insipid. Puerility, he adds, is the common fault of those who affect to say nothing but what is brilliant and extraordinary.

PUFFENDORF (Samuel de) was born in 1631 at Fleh, a little village in Misnia, a province in Upper Saxony; and was son of Elias Puffendorf, minister of that place. After having made great progress in the sciences at Leipzig, he turned his thoughts to the study of the public law, which in Germany consists of the knowledge of the rights of the empire over the princes and states of which it is composed, and those of the princes and states with respect to each other. But though he used his utmost efforts to distinguish himself, he despised those pompous titles which are so much sought for at universities, and never would take the degree of doctor. He accepted the place of governor to the son of Mr Coyet, a Swedish nobleman, who was then ambassador from Sweden to the court of Denmark. For this purpose he went to Copenhagen, but continued not long at ease there; for the war being re-

newed some time after between Denmark and Sweden, he was seized with the whole family of the ambassador. During his confinement, which lasted eight months, as he had no books, and was allowed to see no person, he amused himself by meditating on what he read in Grotius's treatise *De Jure Belli et Pacis*, and the political writings of Mr Hobbes. Out of these he drew up a short system, to which he added some thoughts of his own, and published it at the Hague in 1660, under the title of *Elementa Jurisprudentiæ Universalis*. This recommended him to the elector Palatine, who invited him to the university of Heidelberg, where he founded in his favour a professorship of the law of nature and nations, which was the first of that kind established in Germany. Puffendorf remained at Heidelberg till 1673, when Charles XI. of Sweden gave him an invitation to be professor of the law of nature and nations at Lund; which place the elector Palatine reluctantly allowed him to accept. He went thither the same year; and after that time his reputation greatly increased. Some years after, the king of Sweden sent for him to Stockholm, and made him his historiographer, and one of his counsellors. In 1688, the elector of Brandenburg obtained the consent of his Swedish majesty, that he should come to Berlin, in order to write the history of the elector William the Great; and in 1694 made him a baron. But he died that same year of an inflammation in his feet, occasioned by cutting his nails; having attained his grand climacteric. Of his works, which are numerous, the following are the principal: 1. A Treatise on the Law of Nature and Nations, written in German; of which there is an English translation with Barbeyrac's Notes. 2. An Introduction to the History of the Principal States which at present subsist in Europe; written in German; which has been also translated into English. 3. The History of Sweden, from Gustavus Adolphus's expedition into Germany to the abdication of Queen Christina. 4. The History of Charles Gustavus, two volumes folio, &c.

PUFFIN. See **ALCA**, n° 3.

PUGET (Peter Paul), one of the greatest painters and sculptors France ever produced, though but little noticed by their own writers, was born at Marseilles in 1623. In his youth he was the disciple of Roman, an able sculptor; and then went to Italy, where he studied painting and architecture. In painting he so well imitated the manner of Peter de Cortona, that this painter desired to see him, and entered into a friendship with him. In 1657, a dangerous disorder obliged him to renounce the pencil, and devote himself to sculpture; and his reputation causing him to be invited to Paris, he enjoyed a pension of 1200 crowns, as sculptor and director of the works relating to vessels and galleys. He died at Marseilles in 1695, and has left a number of admirable statues behind him both in France and Italy.

PUGIL, in physic, &c. such a quantity of flowers, seeds, or the like, as may be taken up between the thumb and two fore-fingers. It is reckoned the eighth part of the manipulus or handful.

PULEGIIUM, or *Penny-Royal*. See **MENTHA**.

PULEX, the *FLEA*, in zoology, a genus of insects belonging to the order of aptera. It has two eyes, and

Puffendorf
Pulex.

Pulex.

and six feet fitted for leaping; the feelers are like threads; the rostrum is inflected, setaceous, and armed with a sting; and the belly is compressed.

The generation of this familiar vermin affords something very curious, first discovered by Sig. Diacinto Cestore. Fleas bring forth eggs, or nits, which they deposit on animals that afford them a proper food: these eggs being very round and smooth, usually slip straight down; unless detained by the piles or other inequalities, of the clothes, hairs, &c. Of these eggs are hatched white worms, of a shining pearl colour, which feed on the scurfy substance of the cuticle, the downy matter gathered in the piles of clothes, or other the like substances. In a fortnight they come to a tolerable size, and are very lively and active; and, if at any time disturbed, they suddenly roll themselves into a kind of ball. Soon after this, they come to creep, after the manner of silk-worms, with a very swift motion. When arrived at their size, they hide themselves as much as possible, and spin a silken thread out of their mouth, wherewith they form themselves a small round bag, or case, white within as paper, but without always dirty, and fouled with dust. Here, after a fortnight's rest, the animalcule bursts out, transformed into a perfect flea; leaving its exuvia in the bag. While it remains in the bag, it is milk-white, till the second day before its eruption; when it becomes coloured, grows hard, and gets strength; so that upon its first delivery it springs nimbly away.

The flea, when examined by the microscope, affords a very pleasing object. It is covered all over with black, hard, and shelly scales or plates, which are curiously jointed, and folded over one another in such a manner as to comply with all the nimble motions of the creature. These scales are all curiously polished, and are beset about the edges with short spikes in a very beautiful and regular order. Its neck is finely arched, and much resembles the tail of a lobster: the head also is very extraordinary; for from the snout-part of it there proceed the two fore-legs, and between these is placed the piercer or sucker with which it penetrates the skin to get its food. Its eyes are very large and beautiful, and it has two short horns or feelers. It has four other legs joined all at the breast. These, when it leaps, fold short one within another; and then, exerting their spring all at the same instant, they carry the creature to a surprising distance. The legs have several joints, and are very hairy, and terminate in two long and hooked sharp claws. The piercer or sucker of the flea is lodged between its fore-legs, and includes a couple of darts or lancets; which, after the piercer has made an entrance, are thrust farther into the flesh, to make the blood flow from the adjacent parts and occasion that round red spot, with a hole in the centre of it, vulgarly called a *flea-bite*. This piercer, its sheath opening sideways and the two lancets within it, are very difficult to be seen; unless the two fore-legs, between which they are hid, be cut off close to the head: for the flea rarely puts out its piercer, except at the time of feeding, but keeps it folded inwards; and the best way of seeing it is by cutting off first the head, and then the fore-legs, and then it is usually seen thrust out in convulsions.

By keeping fleas in a glass tube corked up at both ends, but so as to admit fresh air, their several ac-

tions may be observed, and particularly their way of coupling, which is performed tail to tail; the female, which is much the larger, standing on the male. They may also be thus seen to lay their eggs, not all at once, but ten or twelve in a day, for several days successively; which eggs will be afterwards found to hatch successively in the same order. The flea may easily be dissected in a drop of water; and by this means the stomach and bowels, with their peristaltic motion, may be discovered very plainly, as also their testes and penis, with the veins and arteries, though minute beyond all conception. Mr Lieuwenhoek affirms also, that he has seen innumerable animalcules, shaped like serpents, in the semen masculinum of a flea. This blood-thirsty insect, which fattens at the expence of the human species, prefers the more delicate skin of women; but preys neither upon epileptic persons, nor upon the dead or dying. It loves to nestle in the fur of dogs, cats, and rats. The nests of river-swallows are sometimes plentifully stored with them.

Fleas are apterous; walk but little, but leap to a height equal to 200 times that of their own body. This amazing motion is performed by means of the elasticity of their feet, the articulations of which are so many springs. Thus it eludes, with surprising agility, the pursuit of the person on whom it riots.—Among the memorabilia of fleas, one, they say, has been seen to draw a small silver piece of ordnance to which it was fastened, the firing of the gun nowise daunting its intrepidity. The owner carried it about in a little box lined with velvet, every now and then placing it on her arm to let it feed; but winter put an end to the being of this martial flea. Another flea that became slave to an Englishman, had for its daily and easy task to drag its golden chain and padlock, of the weight of one grain. A third flea served as a thrill-horse to an English artist, who had made an ivory coach and six, that carried a coachman with his dog between his legs, a postilion two footmen, and four inside riders. At Surat fleas, bugs, and other voracious vermin are in so great veneration, that they have an hospital endowed, where every night a poor fellow, for hire, suffers himself to be preyed upon. He is fastened naked on a bed, when the feast begins at his expence. In Turkey there is a similar foundation for decayed dogs; an institution less ridiculous than the other. Mercurial ointment, brimstone, a fumigation with the leaves of penny-royal, or fresh-gathered leaves of that plant sewed up in a bag, and laid in the bed, are remedies pointed out as destructive of fleas.

Pulex-Arboreus, in natural history the name given by Mr Reaumur to a very large genus of small animals. They are a kind of half-winged creatures: they have granulated antennæ; and some of them, in their most perfect state, have complete wings. These are distinguished from the others by the name of *musca-pulex* or the *winged-pulex*.

The several species of these creatures are of different colours: some are brown, others yellow: but the most frequent are green. They all feed upon the leaves of trees, which become withered and curled up on their eroding them; and they are so common, that wherever a leaf of a tree is found curled up, or of a different form from the others, it is highly probable these

Pulex.

Barbut's
Genera of
Insects,
p. 330, &

Pulex

animals are on it, or that it is their work. Among trees the willow and the rose are the most infected by them; and among plants, the bean and the poppy. They live a social life, multitudes of males and females being found together. The females are easily distinguished from the males, by their being thicker in the body, and having larger bellies.

It is very wonderful, that of all the known animals of the winged kind, these are the only ones which are viviparous. This is easily seen beyond a possibility of doubt; for, on examining a cluster of them together, it is a common thing to see, by the help of a small magnifier, a female in the act of parturition; and the author* of this account frequently saw the young pulex protruded out, from a passage near the anus of the female, perfectly formed. He had suspected this from the total want of eggs among so numerous a tribe of animals, and from their remarkably speedy propagation, and was thus convinced of it by ocular demonstration.

*Reaumur, History of Insects,

They are armed with a tender and flexile proboscis; with which they seize hold of the young shoots of the tree they live upon, twisting the proboscis round it. These creatures are always seen naked and exposed, standing on the outside of the stalks and leaves, and sucking in their juices for nourishment with their proboscis. But there is another species of them, which are alike viviparous, and agree with them in all respects except in their manner of living. These get into the inner substance of the leaves, like the worms called *ascarides*; and feed on the parenchyma, being defended from all injuries by living between the integuments. In this case, the leaves they bury themselves in become scabrous and deformed, and produce a sort of galls; so that Malpighi erred in supposing all the galls of trees to be produced by the animals hatched of the eggs of ichneumon flies; since these animals, which are viviparous, and are of a very different kind from the worms of the ichneumon flies, equally produce them. A female of the species here treated of has been seen to bring forth seven young ones in a day: and thus from residing alone in the tubercles which she had formed on a leaf, she in a little time becomes the mother of a numerous family; each of which raises its own tumour or gall on the leaf, which at first are small and round, and of a beautiful red like kermes.

Such of these as are of the male species have a certain time of rest, in which they lie buried in a silky matter, and afterwards become winged, flying nimbly about; whereas the females never are able to fly, but remain always half-winged. It is to be observed, however, that there is a different species of winged insects frequently found flying about the female pulices, as well as their own males; so that all the small-winged insects about them are not to be thought of their own species. These do not greatly differ in figure; but the one are harmless, and the others have stings, and hurt any part of the body on which they fix.

Pulex Aquaticus auctorum (*monoculus pulex* of Linnaeus), in entomology, is a species of the genus *MONOCULUS*, which see. It is a most curious insect of the size of a flea, and has been noticed by many writers who have examined its parts with accuracy, and is that which, uniting together in vast numbers, occasions the

beautiful red patches which may be observed in a dry summer season on stagnant waters, giving rise to reports of water being turned to blood, and in the minds of the less informed thought to portend dire events. The other species of the same genus collect on waters in a similar way, and occasion a similar appearance, as has been mentioned under the generic name, to which we refer our readers. See also Swammerdam's *Book of Nature*, p. 39; Baker's *Employment for the Microscope*, p. 302.; Schœffer's *Icon. Inf.*; Sultz. *Inf.* p. 30: De Seer's *Inf.* vol. 7. &c. where there are also excellent figures of it. We have given a figure of it magnified and drawn from life: The outward form of the body, Swammerdam says, is a kind of square; under the eye there is a sharp beak; on the breast are a kind of arms divided into branches like the boughs of trees, and in the abdomen there is a transparent substance with the legs and tail, and in the hinder part of the body, its legs appear placed as it were on the middle of the back: The eyes are almost close together, and are reticulated; the beak is transparent.

It appears that insects of this tribe are enabled to bear the extremes of heat and cold: for Ray, in his *Historia Insectorum*, p. 41, observes, that the *pulex fluviatilis* was met with by Mr Willoughby in a hot bath near Vicenza in Italy the temperature of which was such as to prevent any other living therein; and, on the contrary, O. Fabricius, in his *Fauna Grœlandiæ*, p. 264. mentions the circumstance of the *monoculus pulex* being frequently found under the ice in the stagnant waters of Greenland.

The chego, or *pulex minimus, cutem penetrans, Americanus* of Catesby, is a very small animal found in warm climates. It is a very troublesome insect, especially to negroes and such as are slovenly or go barefooted. They penetrate the skin, under which they lay a bunch of eggs, which swell to the bigness of a small pea or tare. They are exceedingly painful; and unless great care is used in taking them out, they are dangerous. It is about one-fourth the size of a common flea; the figure is considerably magnified. From the mouth issues a hollow tube like that of a common flea, between a pair of antennæ. It has six jointed legs, and something like a tail. Under it is one of its eggs, which is scarcely visible to the naked eye. These animals are a great nuisance to most parts of America between the tropics. See Sir Hans Sloane's, *History of Jamaica*, Introd. p. cxxiv. and vol. ii. 191, 192.

Pulex-Eaters, a name given by naturalists to a sort of worms frequently found on the leaves of trees, where they devour the animals called *pulices arboræi*.

Of these there are several species, which owe their origin to the eggs of different creatures; for there are none of them in their ultimate state in this their time of feeding. According to the different animals whose eggs they are hatched from, these are of different form and structure. Some are hexapodes, or endued with six feet; these belong to the beetle-tribe, and finally change into beetles like the parent animal from whose eggs they sprung. Others have no legs, and are produced from the eggs of flies of various kinds. And, finally, others are genuine caterpillars, though small; but these are the most rare of all.

The two general kinds are the hexapodes, or beetle-worms

Pulex.

Pulley
||
Pulse.

Worms; and the apodes, or fly-worms. The fly which gives origin to the last of these is a four-winged one; and takes care always to deposit her eggs in a place where there are plenty of the pulices, usually on the stalk or young branches of a tree in the midst of large families of them. The worm, as soon as hatched, finds itself in the midst of abundance of food, preying at pleasure on these animals, which are wholly defenceless. The stalks of the elder and woodbine are frequently found covered over with these pulices; and among them there may usually be found one or more of these destroyers feeding at will, sucking in the juices from their bodies, and then throwing away the dry skins. Besides the worms of this four-winged fly, there is one of a two-winged wasp-fly, very destructive of these animals.

PULLEY, in mechanics, one of the five mechanical powers. See **MECHANICS**, p. 739.

PULMO, the **LUNGS**, in **ANATOMY**. See there, n° 117.

PULMONARIA, **LUNGWORT**: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 41st order, *Asperifolia*. The corolla is funnel-shaped, with its throat pervious; the calyx is prismatic and pentagonal. There are several species; of which the most remarkable is the officinalis, common spotted lungwort, or Jerusalem cowslip. This is a native of woods and shady places in Italy and Germany, but has been cultivated in Britain for medicinal use. The leaves are of a green colour, spotted with white; and of a mucilaginous taste, without any smell. They are recommended in phthisis, ulcers of the lungs, &c. but their virtues in these diseases are not warranted by experience.

PULO PINANG. See *PRINCE of Wales's Island*.

PULP, in pharmacy, the fleshy and succulent parts of fruits extracted by infusion or boiling, and passed through a sieve.

PULPIT, an elevated place in a church, whence sermons are delivered. The French give the same name to a reading-desk.

PULPITUM, in the Grecian and Roman theatres, was a place where the players performed their parts. It was lower than the scena, and higher than the orchestra. It nearly answered to what we call the stage, as distinguished from the pit and galleries.—*Pulpitum* was also a moveable desk or pulpit, from which disputants pronounced their dissertations, and authors recited their works.

PULSE, in the animal economy, denotes the beating or throbbing of the heart and arteries.

No doctrine has been involved in more difficulties than that of pulses; since, in giving a physiological account of them, physicians have espoused quite opposite sentiments; whilst some doubt whether the pulse is owing to the systole or diastole; as also, whether the motion of the heart and arteries is one and the same, for a moment of time.

With regard to motion, the pulses are reckoned only four; great and little, quick and slow. When quickness and greatness are joined together, it becomes violent; and when it is little and slow it is called a *weak pulse*. They are also said to be *frequent* and *rare*, *equal* and *unequal*; but these are not the essential affections

of motion. Frequency and quickness are often confounded with each other. A pulse is said to be *hard* or *soft*, with regard to the artery, according as it is tense, renitent, and hard, or flaccid, soft and lax: for the disposition of the arteries contributes greatly to the change of the pulse; wherefore it sometimes happens, that the pulse in both arms is not alike which is very common in a hemiplexy. Add to these a convulsive pulse, which does not proceed from the blood, but from the state of the artery; and is known by a tremulous subsultory motion, and the artery seems to be drawn upwards: this, in acute fevers, is the sign of death; and is said to be the pulse in dying persons, which is likewise generally unequal and intermitting. A *great* pulse shows a more copious afflux of the blood to the heart; and from thence into the arteries; a *little* pulse the contrary.

The pulses of persons differ according to the largeness of the heart and vessels, the quantity and temperies of the blood, the elastic force of the canals; as also with regard to the sex, age, season, air, motion, food, sleep, watchings, and passions of the mind. The pulse is larger and more quick in men than in women; in the bilious and sanguineo-bilious, than in the phlegmatic and melancholic. Those who are lean, with tense fibres and large vessels, have a greater and a stronger pulse, than those that are obese, with lax fibres and small vessels; whence they are more healthy, robust, and apt for labour. In children, the pulse is quick and soft; in adults greater and more violent. In the old, it is commonly great, hard, and slow. Labour, motion, and exercise of the body, increase the circulation of the blood, the excretions, and particularly respiration; rest renders the circulation slow and weak; intense speaking increases the circulation, and consequently renders the pulse large and quick. In watching, the pulse is more evident; in sleep, more slow and languid. After drinking hot things, such as coffee and tea, or hot bath-waters, as well as after meals, the pulse vibrates more quick. But nothing produces a greater change in the pulse than affections of the mind: in terror, it is unequal, small, and contracted; in joy, frequent and great; in anger, quick and hard; in sadness, slow, small, deep, and weak; and in intense study, languid and weak. With regard to the air, when, after the predominancy of a west or south wind, it becomes north or east, the pulse is stronger and larger; as also when the quicksilver rises in the barometer. But when the atmosphere is dense, humid, rainy, with a long south wind; as also where the life is sedentary, the sleep long, and the season autumnal, the pulse is languid and small, and the perspiration decreased. In May it is great sometimes and violent; in the middle of summer, quick but weak; in the autumn, slow, soft, and weak; in the winter, hard and great. A drastic purge and an emetic render the pulse hard, quick, and weak, with loss of strength; chalybeates, and the bark, render it great and robust, and the complexion lively; volatiles amplify and increase the pulse; acids and nitrous remedies refrigerate the body, and appease the pulse; opiates and the like render it small and weak, and decrease the elasticity of the solids; and poisons render it small, contracted, and hard. When the quantity of the blood is too great, bleeding raises the pulse.

PULSE, is also used for the stroke with which any medium

Pulse.

Pulteney.
Palveriza-
tion.

medium is affected by the motion of light, sound, &c. through it.

Sir Isaac Newton demonstrates, that the velocities of the pulses in an elastic fluid medium (whose elasticity is proportionable to its density) are in a ratio compounded of half the ratio of the elastic force directly, and half the ratio of the density inversely; so that in a medium whose elasticity is equal to its density, all pulses will be equally swift.

PULSE, in botany, a term applied to all those grains or seeds which are gathered with the hand; in contradistinction to corn, &c. which are reaped, or mowed: or, It is the seed of the leguminous kind of plants, as beans, vetches, &c. but is by some used for artichokes, asparagus, &c.

PULTENEY (William), the famous opposer of Sir Robert Walpole in parliament, and afterward earl of Bath, was descended from one of the most ancient families in the kingdom, and was born in 1682. Being well qualified in fortune, he early procured a seat in the house of commons, and distinguished himself as a warm partisan against Queen Anne's ministry; whose errors he had sagacity to detect, and spirited eloquence to expose. When King George I. came to the throne, Mr Pulteney was made secretary at war, and soon after cofferer to the king's household; but the good understanding between this gentleman and Sir Robert Walpole, who then acted as prime minister, was interrupted in 1725, on a suspicion that Walpole was desirous of extending the limits of prerogative, and of promoting the interests of Hanover, to the prejudice of those of Britain. His opposition to Sir Robert was indeed carried to such indiscriminate lengths, that some have been of opinion he often acted against measures beneficial to the public, merely from personal motives. It would be impracticable here to trace his parliamentary conduct: so it must suffice to observe in general, that he became so obnoxious to the crown, that in 1731 the king called for the council-book, and with his own hand struck out his name from the list of the privy-councillors; a proceeding that only served to inflame his resentment and increase his popularity. Thus he still continued to attack the minister with a severity of eloquence and sarcasm that worked every antagonist; so that Sir Robert was heard to declare, he dreaded that man's tongue more than another man's sword. At length, when Walpole found the place of prime minister no longer tenable, and resigned in 1741, among other promotions Mr Pulteney resumed his place in the privy-council, and was created earl of Bath; a title purchased at the expence of that popularity which afterward he naturally enough affected to contemn. In 1760, toward the close of the war, he published *A Letter to two Great Men*, recommending proper articles to be insisted on in a treaty of peace; which, though the writer was then unknown, was greatly applauded, and went through several impressions. He died in 1764; and as his only son died before him, the title became extinct.

PULVERIZATION, the art of pulverizing, or reducing a dry body into a fine powder; which is performed, in friable bodies, by pounding or beating them in a mortar, &c.; but to pulverize malleable ones, other methods must be taken. To pulverize lead, or

tin, the method is this: Rub a round wooden box all over the inside with chalk; pour a little of the melted metal nimbly into the box; when shutting the lid, and shaking the box briskly, the metal will be reduced to powder.

PUMEX, the **PUMICE-STONE**, a substance frequently thrown out of volcanoes, though there are many which are never known to throw it out. It is very full of pores and blisters; in consequence of which it is specifically very light, and resembles the frothy slag produced in our iron furnaces. It is of two colours, black and white; the former being that which it has when thrown out of the volcano; the latter, as Cronstedt conjectures, being perhaps faded and bleached. M. Magellan considers it rather as a volcanic ejection than a volcanic production; and describes it as of a white, reddish-brown, grey, or black colour. It is of a rough and porous consistence, being made up of slender fibres parallel to each other, and very light, so that it swims on water. It strikes fire with steel, though with difficulty, and seems originally to have been an asbestos decomposed by the action of fire; but, on observing the appearance of that glassy slag produced in the iron-furnaces, which entirely resembles the pumice-stone, and is produced from the calcareous fluxes used to promote the fusion of the ore, our author is of opinion that the formation of pumice may be rather attributed to that kind of froth which must be formed at the top of the melted matters in the volcanic crater. An hundred parts, according to Bergman, contain from 6 to 15 of magnesia, with a small proportion of calcareous earth, and the greatest part siliceous. Another kind of pumice, which seems to be a ferruginous granite altered by fire, has been discovered by Dolomieu at Stromboli.

Pumice-stone is used in some mechanical arts; as for rubbing and smoothing the surface of metals, wood, pasteboard, and stone; for which it is well fitted by reason of its harsh and brittle texture; thus scouring and carrying off the little inequalities from the surfaces just mentioned.

PUMICE-STONE. See the preceding article.

PUMP, an hydraulic machine for raising water by means of the pressure of the atmosphere.

It would be an entertaining and not an unimportant piece of information to learn the progressive steps by which the ingenuity of man has invented the various methods of raising water. A pump must be considered as the last step of this progress. Common as it is, and overlooked even by the curious, it is a very abstruse and refined invention. Nothing like it has been found in any of the rude nations whom the restless spirit of the Europeans has discovered, either in the new continent of America or the islands of the Pacific Ocean. Nay, it was unknown in the cultivated empire of China at the time of our arrival there by sea; and it is still a rarity everywhere in Asia, in places unfrequented by the Europeans. It does not appear to have been known to the Greeks and Romans in early times; and perhaps it came from Alexandria, where physical and mathematical science was much cultivated by the Greek school under the protection of the Ptolemies. The performances of Ctesibius and Hero are spoken of by Pliny and Vitruvius as curious novelties.

Pumex
||
Pump.

Of the invention of pumps.

Pump. ties (A). It is perhaps not difficult to trace the steps by which those mechanicians were led to the invention. The Egyptian wheel was a common machine all over Asia, and is still in use in the remotest corners, and was brought by the Saracens into Spain, where it is still very common under its ancient name *NORIA*. The Danish missionaries found in a remote village in the kingdom of Siam the immediate offspring of the *noria* (*Lettres Edifiantes et Curieuses*.) It was a wheel turned by an afs, and carrying round, not a string of earthen pots, but a string of wisps of hay, which it drew through a wooden trunk. This rude chain-pump was in frequent use for watering the rice fields. It is highly probable that it is of great antiquity, although we do not recollect its being mentioned by any of the Greek or Roman writers. The Arabs and Indians were nothing less than innovators; and we may suppose with great safety, that what arts we now find among them they possessed in very remote periods. Now the step from this to the pump is but short, though it is nice and refined; and the forcing pump of Ctesibius is the easiest and most natural.

Plate

2
Ctesibius's pump.

Let AB (fig. 1.) be the surface of the water in the well, and D the height where it is to be delivered. Let DC be a long wooden trunk, reaching as deep under water as possible. Let the rope EF be fitted with its knot of hay F. When it is drawn up through the trunk, it will bring up along with it all the water lying between C and A, which will begin to run out by the spout D as soon as the knot gets to G, as far below D as C is below A. All this is very obvious; and it required but little reflection to be assured, that if F was let down again, or pushed down, by a rod instead of a rope, it would again perform the same office. Here is a very simple pump. And if it was ever put in practice, it behoved to show the supporting power of the atmosphere, because the water would not only be lifted by the knot, but would even follow it. The imperfection of this pump behoved to appear at first sight, and to suggest its remedy. By pushing down the knot F, which we shall henceforward call the *piston*, all the force expended in lifting up the water between A and G is thrown away, because it is again let down. A valve G, at the bottom, would prevent this. But then there must be a passage made for the water by a lateral tube KBD (fig. 2.) And if this be also furnished with a valve H, to prevent its losing the water, we have the pump of Ctesibius, as sketched in fig. 2. The valve is the great refinement: but perhaps even this had made its appearance before in the *noria*. For, in the more perfect kinds of these machines, the pots have a stop or valve in their bottom, which hangs open while the

pot descends with its mouth downwards, and then allows it to fill readily in the cistern; whereas, without the valve, it would occasion a double load to the wheel. If we suppose that the valve had made its appearance so early, it is not improbable that the common pump sketched in fig. 3. was as old as that of Ctesibius. For a further description of the pump of Ctesibius as it was used by the ancients, and of those pumps which have been deduced from it and are now in common use, see *HYDROSTATICS* n° 28—32. In this place we shall first give a short description of the chief varieties of these engines, considering them in their simplest form, and we shall explain in very general terms their mode of operation. We shall then give a concise and popular theory of their operation, furnishing principles to direct us in their construction; and we shall conclude with the description of a few peculiarities which may contribute to their improvement or perfection.

There are but two sorts of pumps which essentially differ; and all the varieties that we see are only modifications of these. One of these original pumps has a solid piston; the other has a piston with a perforation and a valve. We usually call the first a *FORCING PUMP*, and the second a *LIFTING OR SUCKING PUMP*.

Fig. 2. is a sketch of the forcing pump in its most simple form and situation. It consists of a hollow cylinder ACca, called the *WORKING BARREL*, open at both ends, and having a valve G at the bottom, opening upwards. This cylinder is filled by a solid piston EF, covered externally with leather or tow, by which means it fits the box of the cylinder exactly, and allows no water to escape by its sides. There is a pipe KHD, which communicates laterally with this cylinder, and has a valve at some convenient place H, as near as possible to its junction with the cylinder. This valve also opens upwards. This pipe, usually called the *RISEING PIPE*, or *MAIN*, terminates at the place D, where the water must be delivered.

Now suppose this apparatus set into the water, so that the upper end of the cylinder may be under or even with the surface of the water AB; the water will open the valve G, and after filling the barrel and lateral pipe, will also open the valve H, and at last stand at an equal height within and without. Now let the piston be put in at the top of the working barrel, and thrust down to K. It will push the water before it. This will shut the valve G, and the water will make its way through the valve H, and fill a part Bb of the rising pipe, equal to the internal capacity of the working barrel. When this downward motion of the piston ceases, the valve H will fall down by its own weight and shut this passage. Now let the piston be drawn up again: The valve H hinders the water in the

(A) In the early Greek writings, it does not appear that the words *ἄντρος*, *ἄντρεν*, *ἄντλια*, &c. were used to express any thing like what we call a pump. In all these passages the words either express generally the drawing of water, or, more particularly, the drawing it with a bucket or something similar. *ἄντρος*, which is the primitive, is a drain, sink, or receptacle for collecting scattered water, either for use, or to get rid of it; hence it came to signify the sink or well of a ship; and *ἄντρεν* was synonymous with our verb "to bale the boat." (*Odyss.* O. 476. M. 411. *Euryp. Hecuba*, 1025). *Ἀντλίων* is the vessel or bucket with which water is drawn, *Ἀντλια* is the service (generally a punishment) of drawing water. *Ἀντρεν*, "to draw water with a bucket": hence the force of Aristotle's expression (*Oecon.* I). *τῷ γὰρ ἡθμῶ ἄντρεν τεύτ' ἔστι*. See even the late authority of the New Testament, John ii. 8.; iv. 7. 11. Here *ἄντλημα* is evidently something which the woman brought along with her; probably a bucket and rope.

Pump. the rising pipe from returning into the working barrel. But now the valve G is opened by the pressure of the external water, and the water enters and fills the cylinder as the piston rises. When the piston has got to the top, let it be thrust down again: The valve G will again be shut, and the water will be forced through the passage at H, and rise along the main, pushing before it the water already there, and will now have its surface at L. Repeating this operation, the water must at last arrive at D, however, remote, and the next stroke would raise it to e ; so that during the next rise of the piston the water in e D will be running off by the spout.

The effect will be the same whatever is the position of the working barrel, provided only that it be under water. It may lie horizontally or sloping, or it may be with its mouth and piston rod undermost. It is still the same forcing pump, and operates in the same manner, and by the same means, viz. the pressure of the surrounding water.

The external force which must be applied to produce this effect is opposed by the pressure exerted by the water on the opposite face of the piston. It is evident, from the common laws of hydrostatics, that this opposing pressure is equal to the weight of a pillar of water, having the face of the piston for its base, and the perpendicular height d A of the place of delivery above the surface of the water AB in the cistern for its height. The form and dimensions of the rising pipe are indifferent in this respect, because heavy fluids press only in the proportion of their perpendicular height. Observe that it is not d F, but d A, which measures this pressure, which the moving force must balance and surmount. The whole pressure on the under surface Ff of the piston is indeed equal to the weight of the pillar d Ff δ ; but part of this is balanced by the water AFfa. If indeed the water does not get into the upper part of the working barrel, this compensation does not obtain. While we draw up the piston, this pressure is removed, because all communication is cut off by the valve H, which now bears the whole pressure of the water in the main. Nay, the ascent of the piston is even assisted by the pressure of the surrounding water. It is only during the descent of the piston therefore that the external force is necessary.

Observe that the measure now given of the external force is only what is necessary for *balancing* the pressure of the water in the rising pipe. But in order that the pump may perform work, it must *surmount* this pressure, and cause the water to issue at D with such a velocity that the required quantity of water may be delivered in a given time. This requires force, even although there were no opposing pressure; which would be the case if the main were horizontal. The water fills it, but it is at rest. In order that a gallon, for instance, may be delivered in a second, the whole water in the horizontal main must be put in motion with a certain velocity. This requires force. We must therefore always distinguish between the state of equilibrium and the state of actual working. It is the equilibrium only that we consider at present: and no more is necessary for understanding the operation of the different species of pumps. The other force is of much more intricate investigation, and will be considered by itself

The simplest form and situation of the lifting pump is represented by the sketch fig. 3. The pump is immersed in the cistern till both the valve G and piston F are under the surface AB of the surrounding water. By this means the water enters the pump, opening both valves, and finally stands on a level within and without. **Pump.** 5 Lifting pump.

Now draw up the piston to the surface A. It must lift up the water which is above it (because the valve in the piston remains shut by its own weight); so that its surface will now be at a , Aa being made equal to AF. In the mean time the pressure of the surrounding water forces it into the working barrel, through the valve G; and the barrel is now filled with water. Now, let the piston be pushed down again; the valve G immediately shuts by its own weight, and in opposition to the endeavours which the water in the barrel makes to escape this way. This attempt to compress the water in the barrel causes it to open the valve F in the piston; or rather, this valve yields to our endeavour to push the piston down through the water in the working barrel. By this means we get the piston to the bottom of the barrel; and it has now above it the whole pillar of water reaching to the height a . Drawing up the piston to the surface A a second time, must lift this double column along with it, and its surface now will be at b . The piston may again be thrust down through the water in the barrel, and again drawn up to the surface which will raise the water to c . Another repetition will raise it to d ; and it will now show itself at the intended place of delivery. Another repetition will raise it to e ; and while the piston is now descending to make another stroke, the water in ed will be running off through the spout D; and thus a stream will be produced, in some degree continual, but very unequal. This is inconvenient in many cases: thus, in a pump for domestic uses, such a hobbling stream would make it very troublesome to fill a bucket. It is therefore usual to terminate the main by a cistern LMNO, and to make the spout small. By this means the water brought up by the successive strokes of the piston rises to such a height in this cistern, as to produce an efflux by the spout nearly equable. The smaller we make the spout D the more equable will be the stream; for when the piston brings up more water than can be discharged during its descent, some of it remains in the cistern. This, added to the supply of next stroke, makes the water rise higher in the cistern than it did by the preceding stroke. This will cause the efflux to be quicker during its descent of the piston, but perhaps not yet sufficiently quick to discharge the whole supply. It therefore rises higher next stroke; and at last it rises so high that the increased velocity of efflux makes the discharge precisely balance the supply. Now, the quantity supplied in each stroke is the same, and occupies the same room in the cistern at top; and the surface will sink the same number of inches during the descent of the piston, whether that surface has been high or low at the beginning. But because the velocities of the efflux are as the square roots of the heights of the water above the spout, it is evident that a sink of two or three inches will make a smaller change in the velocity of efflux when this height and velocity are great. This seems but a trifling observation; but it serves to illustrate a thing to be considered afterwards, which is important and abstruse, but perfectly similar to this. **Pump.** 6 Its mode of operating.

Pump.

It is evident, that the force necessary for this operation must be equal to the weight of the pillar of water $d A a D$, if the pipe be perpendicular. If the pump be standing allope, the pressure which is to be balanced is still equal to the weight of a pillar of water of this perpendicular height, and having the surface of the piston for its base.

Such is the simplest, and, we may add, by far the best, form of the forcing and lifting pumps; but it is not the most usual. Circumstances of convenience, economy, and more frequently of fancy and habit, have caused the pump-makers to deviate greatly from this form. It is not usual to have the working barrel in the water; this, especially in deep wells, makes it of difficult access for repairs, and requires long piston rods. This would not do in a forcing pump, because they would bend.

7
Effect of
giving the
piston a
longer
stroke.

We have supposed, in our account of the lifting pump, that the rise of the piston always terminated at the surface of the water in the cistern. This we did in order that the barrel might always be filled by the pressure of the surrounding water. But let us suppose that the rise of the piston does not end here, and that it is gradually drawn up to the very top: it is plain that the pressure of the atmosphere is by this means taken off from the water in the pipe (see PNEUMATICS), while it remains pressing on the water of the cistern. It will therefore cause the water to follow the piston as it rises through the pipe, and it will raise it in this way 33 feet at a medium. If, therefore, the spout D is not more than 33 feet above the surface of the water in the cistern, the pipe will be full of water when the piston is at D . Let it be pushed down to the bottom; the water will remain in the pipe, because the valve G will shut: and thus we may give the piston a stroke of any length not exceeding 33 feet. If we raise it higher than this, the water will not follow; but it will remain in the pipe, to be lifted by the piston, after it has been pushed down through it to the bottom.

8
Inconveni-
ent and un-
necessary.

But it is not necessary, and would be very inconvenient, to give the piston so long a stroke. The great use of a pump is to render effectual the reciprocation of a short stroke which we can command, while such a long stroke is generally out of our power. Suppose that the piston is pushed down only to b ; it will then have a column $b f$ incumbent on it, and it will lift this column when again drawn up. And this operation may be repeated like the former, when the piston was always under water; for the pressure of the atmosphere will always cause the water to follow the piston to the height of 33 feet.

Nor is it necessary that the fixed valve G be placed at the lower orifice of the pipe, nor even under water. For, while things are in the state now described, the piston drawn up to f , and the whole pipe full of water; if we suppose another valve placed at b above the surface of the cistern, this valve can do no harm. Now let the piston descend, both valves G and b will shut. G may now be removed, and the water will remain supported in the space $b G$ by the air; and now the alternate motions of the piston will produce the same effect as before.

9
Effect of
the weight
of the wa-
ter and
pressure of
the atmo-
sphere.

We found in the former case that the piston was carrying a load equal to the weight of a pillar of water of the height AD , because the surrounding water could only support it at its own level. Let us see what change is produced by the assistance of the pressure of the at-

VOL. XV.

mosphere. Let the under surface of the piston be at b ; when the piston was at f , 33 feet above the surface of the cistern, the water was raised to that height by the pressure of the atmosphere. Suppose a partition made at b by a thin plate, and all the water above it taken away. Now pierce a hole in this plate. The pressure of the atmosphere was able to carry the whole column $f a$. Part of this column is now removed, and the remainder is not a balance for the air's pressure. This will therefore cause the water to spout up through this hole and rise to f . Therefore the under surface of this plate is pressed up by the contiguous water with a force equal to the weight of that pillar of water which it formerly supported; that is, with a force equal to the weight of the pillar $b f$. Now, the under surface of the piston, when at b , is in the same situation. It is pressed upwards by the water below it, with a force equal to the weight of the column $f b$: But it is pressed downwards by the whole pressure of the atmosphere, which presses on all bodies; that is, with the weight of the pillar $f a$. On the whole, therefore, it is pressed downwards by a force equal to the difference of the weights of the pillars $f a$ and $f b$; that is, by a force equal to the weight of the pillar $b a$.

It may be conceived better perhaps in this way. When the piston was under the surface of the water in the cistern, it was equally pressed on both sides, both by the water and atmosphere. The atmosphere exerted its pressure on it by the intervention of the water; which being, to all sense, a perfect fluid, propagates every external pressure undiminished. When the piston is drawn up above the surface of the pit-water, the atmosphere continues to press on its upper surface with its whole weight, through the intervention of the water which lies above it; and its pressure must therefore be added to that of the incumbent water. It also continues to press on the under surface of the piston by the intervention of the water; that is, it presses this water to the piston. But, in doing this, it carries the weight of this water which it is pressing on the piston. The pressure on the piston therefore is only the excess of the whole pressure of the atmosphere above the weight of the column of water which it is supporting. Therefore the difference of atmospheric pressure on the upper and under surfaces of the piston is precisely equal to the weight of the column of water supported in the pipe by the air. It is not, however, the individual weight of this column that loads the piston; it is the part of the pressure of the atmosphere on its upper surface, which is not balanced by its pressure on the under surface.

In attempting therefore to draw up the piston, we have to surmount this unbalanced part of the pressure of the atmosphere, and also the weight of the water which lies above the piston, and must be lifted by it: and thus the whole opposing pressure is the same as before, namely, the weight of the whole vertical pillar reaching from the surface of the water in the cistern to the place of delivery. Part of this weight is immediately carried by the pressure of the atmosphere; but, in lieu of it, there is an equal part of this pressure of the atmosphere abstracted from the under surface of the piston, while its upper surface sustains its whole pressure.

So far, then, these two states of the pump agree.— But they differ exceedingly in their mode of operation; and there are some circumstances not very obvious which must be attended to, in order that the pump may deli-

Pump.

10
Other cir-
cumstances
to be at-
tended to.

Pump. ver any water at the spout D. This requires, therefore, a serious examination.

Let the fixed valve G (fig. 4.) be supposed at the surface of the cistern water. Let $M m$ be the lowest, and $N n$ the highest, positions of the piston, and let $HA = b$ be the height of a column of water equiponderant with the atmosphere.

When the pump is filled, not with water, but with air, and the piston is in its lowest position, and all in equilibrio, the internal air has the same density and elasticity with the external. The space $MA a m$, therefore, contains air of the common density and elasticity. These may be measured by b , or the weight of a column of water whose height is b . Now, let the piston be drawn up to $N n$. The air which occupied the space $MA a m$ now occupies the space $NA a n$, and its density is now $\frac{MA a m}{NA a n}$. Its elasticity is now diminished, be-

ing proportionable to its density (see PNEUMATICS), and no longer balances the pressure of the atmosphere. The valve G will therefore be forced up by the water, which will rise to some height SA. Now let the piston again descend to $M m$. It cannot do this with its valve shut; for when it comes down so far as to reduce the air again to its common density, it is not yet at M , because the space below it has been diminished by the water which got into the pipe, and is retained there by the valve G. The piston valve, therefore, opens by the air which we thus attempt to compress, and the superfluous air escapes. When the piston has got to M , the air is again of the common density, and occupies the space $MS s m$. Now draw the piston up to N . This air will expand into the space $NS s n$, and its density will be reduced to $\frac{MS s m}{NS s n}$, and its elasticity will no longer balance the pressure of the atmosphere, and more water will enter, and it will rise higher. This will go on continually. But it may happen that the water will never rise so high as to reach the piston, even though not 33 feet above the water in the cistern: For the successive diminutions of density and elasticity are a series of quantities that decrease geometrically, and therefore will have a limit. Let us see what determines this limit.

At whatever height the water stands in the lower part of the pipe, the weight of the column of water $SA as$, together with the remaining elasticity of the air above it, exactly balances the pressure of the atmosphere (see PNEUMATICS, no 108.) Now the elasticity of the air in the space $NS s n$ is equal to $b \times \frac{MS s m}{NS s n}$. Therefore, in the case where the limit obtains, and the water rises no farther, we must have $b = AS + b \frac{MS s m}{NS s n}$, or, because the column is of the same diameter throughout, $b = AS + b \frac{MS}{NS}$ and $\frac{MS}{NS} b = b - AS = HS$, and $NS : MS = HA : HS$, and $NS - MS : NS = HA - HS : HA$, or $NM : NS = AS : AH$, and $NM \times AH = NS \times AS$.—Therefore, if AN , the distance of the piston in its highest position from the water in the cistern, and NM the length of its stroke, be given there is a certain determined height AS to which the water can be raised by the pressure of the air: For AH is a constant quan-

tity; and therefore when MN is given, the rectangle $AS \times SN$ is given. If this height AS be less than that of the piston in its lowest position, the pump will raise no water, although AN may be less than AH . Yet the same pump will raise water very effectually, if it be first of all filled with water; and we have seen professional engineers much puzzled by this capricious failure of their pumps. A little knowledge of the principles would have prevented their disappointment.

To insure the delivery of water by the pump, the stroke must be such that the rectangle $MN \times AH$ may be greater than any rectangle that can be made of the parts of AN , that is, greater than the square of half AN . Or, if the length of the stroke be already fixed by other circumstances, which is a common case, we must make AN so short that the square of its half, measured in feet, shall be less than 33 times the stroke of the piston.

Suppose that the fixed valve, instead of being at the surface of the water in the cistern, is at S , or any where between S and A , the performance of the pump will be the same as before: But if it be placed anywhere above S , it will be very different. Let it be at T . It is plain that when the piston is pushed down from N to M , the valve at T prevents any air from getting down; and therefore, when the piston is drawn up again, the air contained in the space $MT t m$ will expand into the space $NT t n$, and its density will be $\frac{MT}{NT}$. This is less

than $\frac{MS}{NS}$, which expresses the density of the air which

was left in the space $TS st$ by the former operations.—The air, therefore in $TS st$ will also expand, will open the valve, and now the water will rise above S . The proportion of NS to NT may evidently be such that the water will even get above the valve T . This diminishes the space $NT t n$; and therefore, when the piston has been pushed down to M , and again drawn up to N , the air will be still more rarefied, and the water will rise still higher. The foregoing reasoning, however, is sufficient to show that there may still be a height which the water will not pass, and that this height depends on the proportion between the stroke of the piston and its distance from the water in the cistern. We need not give the determination, because it will come in afterwards in combination with other circumstances. It is enough that the reader sees the physical causes of this limitation: And, lastly, we see plainly that the utmost security will be given for the performance of the pump, when the fixed valve is so placed that the piston, when in its lowest position, shall come into contact with it. In this case, the rarefaction of the air will be the completest possible; and, if there were no space left between the piston and valve, and all were perfectly air-tight, the rarefaction would be complete, and the valve might be any thing less than 33 feet from the surface of the water in the cistern.

But this perfect contact and tightness is unattainable; and though the pump may be full of water, its continual downward pressure causes it to filtrate slowly through every crevice, and the air enters through every pore, and even disengages itself from the water, with which a considerable portion had been chemically combined. The pump by this means loses water, and it requires several strokes of brisk working to fill it again: and

Pump.

Mode of insuring the delivery of water.

12 Valves not easily kept air-tight.

Pump.

and if the leathers have become dry, so much admission may be given to the air, that the pump will not fill itself with water by *any working*. It is then necessary to pour water into it, which shuts up these passages, and soon sets all to rights again. For these reasons, it is always prudent to place the fixed valve as low as other circumstances will permit, and to make the piston rod of such a length, that when it is at the bottom of its stroke it shall be almost in contact with the valve. When we are not limited by other circumstances, it is evident that the best possible form is to have both the piston and the fixed valve under the surface of the water of the cistern. In this situation they are always wet and air-tight. The chief objection is, that by this disposition they are not easily come at when needing repair. This is a material objection in deep mines. In such situations, therefore, we must make the best compensation of different circumstances that we can. It is usual to place the fixed valve at a moderate distance from the surface of the water, and to have a hole in the side of the pipe, by which it may be got out. This is carefully shut up by a plate firmly screwed on, with leather or cement between the parts. This is called the *clack door*. It would, in every case, be very proper to have a fixed valve in the lower end of the pipe. This would combine all advantages. Being always tight, the pipe would retain the water, and it would leave to the valve above it its full effect of increasing the rarefaction. A similar hole is made in the working barrel, a little above the highest position of the piston. When this needs repair, it can be got at through this hole, without the immense trouble of drawing up the whole rods.

Thus we have conducted the reader step by step, from the simplest form of the pump to that which long experience has at last selected as the most generally convenient. This we shall now describe in some detail.

13
Description of the
sucking-
pump.

The **SUCKING PUMP** consists of two pipes DCCD, BAAB (fig. 5.); of which the former is called the *Barrel*, or the *Working Barrel*, and the other is called the *Suction-pipe*, and is commonly of a smaller diameter.—These are joined by means of flanches E, F, pierced with holes to receive screwed bolts. A ring of leather, or of lead, covered with a proper cement, is put between them; which, being strongly compressed by the screw-bolts, renders the joint perfectly air-tight.—The lower end A of the suction-pipe is commonly spread out a little to facilitate the entry of the water, and frequently has a grating across it at AA to keep out filth or gravel. This is immersed in the standing water YZ. The working barrel is cylindrical, as evenly and smoothly bored as possible, that the piston may fill it exactly through its whole length, and move along it with as little friction as may be consistent with air-tightness.

The piston is a sort of truncated cone OPKL, generally made of wood not apt to split, such as elm or beech. The small end of it is cut off at the sides, so as to form a sort of arch OQP, by which it is fastened to the iron rod or spear. It is exhibited in different positions in figures 6, 7. which will give a more distinct notion of it than any description. The two ends of the conical part may be hooped with brass. This cone has its larger end surrounded with a ring or band of strong leather fastened with nails, or by a copper hoop, which is driven on it at the smaller end. This band should reach to some distance beyond the base of

the cone; the farther the better: and the whole must be of uniform thickness all round, so as to suffer equal compression between the cone and the working barrel. The seam or joint of the two ends of this band must be made very close, but not sewed or stitched together. This would occasion bumps or inequalities, which would spoil its tightness; and no harm can result from the want of it, because the two edges will be squeezed close together by the compression in the barrel. It is by no means necessary that this compression be great. This is a very detrimental error of the pump-makers. It occasions enormous friction, and destroys the very purpose which they have in view, viz. rendering the piston air-tight; for it causes the leather to wear through very soon at the edge of the cone, and it also wears the working barrel. This very soon becomes wide in that part which is continually passed over by the piston, while the mouth remains of its original diameter, and it becomes impossible to thrust in a piston which shall completely fill the worn part. Now, a very moderate pressure is sufficient for rendering the pump perfectly tight, and a piece of glove leather would be sufficient for this purpose, if loose or detached from the solid cone; for suppose such a loose and flexible, but impervious, band of leather put round the piston, and put into the barrel; and let it even be supposed that the cone does not compress it in the smallest degree to its internal surface.—Pour a little water carefully into the inside of this sort of cup or dish; it will cause it to swell out a little, and apply itself close to the barrel all round, and even adjust itself to all its inequalities. Let us suppose it to touch the barrel in a ring of an inch broad all round. We can easily complete the force with which it is pressed. It is half the weight of a ring of water an inch deep and an inch broad. This is a trifle, and the friction occasioned by it not worth regarding; yet this trifling pressure is sufficient to make the passage perfectly impervious, even by the most enormous pressure of a high column of incumbent water; for let this pressure be ever so great, the pressure by which the leather adheres to the barrel always exceeds it, because the incumbent fluid has no *preponderating* power by which it can force its way between them, and it must insinuate itself precisely so far, that its pressure on the inside of the leather shall still exceed, and only exceed, the pressure by which it endeavours to insinuate itself; and thus the piston becomes perfectly tight with the smallest possible friction. This reasoning is perhaps too refined for the uninstructed artist, and probably will not persuade him. To such we could recommend an examination of the pistons and valves contrived and executed by that artist, whose skill far surpasses our highest conceptions, the all-wise Creator of this world. The valves which shut up in the passages of the veins, and this in places where an extravasation would be followed by instant death, are cups of thin membrane, which adhere to the sides of the channel about half way round, and are detached in the rest of their circumference. When the blood comes in the opposite direction, it pushes the membrane aside, and has a passage perfectly free. But a stagnation of motion allows the tone of the muscular (perhaps) membrane, to restore it to its natural shape, and the least motion in the opposite direction causes it instantly to clap close to the sides of the vein, and then no pressure whatever can force a passage. We shall recur

to this again, when describing the various contrivances of valves, &c. What we have said is enough for supporting our directions for constructing a tight piston. But we recommended thick and strong leather, while our present reasoning seems to render thin leather preferable. If the leather be thin, and the solid piston in any part does not press it gently to the barrel, there will be in this part an unbalanced pressure of the incumbent column of water, which would instantly burst even a strong leather bag; but when the solid piston, covered with leather, exactly fills the barrel, and is even pressed a little to it, there is no such risk; and now that part of the leather band which reaches beyond the solid piston performs its office in the completest manner. We do not hesitate, therefore, to recommend this form of a piston, which is the most common and simple of all, as preferable, when well executed, to any of those more artificial, and frequently very ingenious, constructions, which we have met with in the works of the first engineers. To proceed, then, with our description of the sucking-pump.

18
Further de-
scription of
the suck-
ing-pump.

At the joining of the working barrel with the suction pipe there is a hole H, covered with a valve opening upwards. This hole H is either made in a plate which makes a part of the suction-pipe, being cast along with it, or it is made in a separate plate. This last is the most convenient, being easily removed and replaced. Different views are given of this valve in fig. 8, 9, 10. The diameter EF (fig. 10.) of this plate is the same with that of the flanches, and it has holes corresponding to them, through which their bolts pass which keep all together. A ring of thick leather NKL is applied to this plate, having a part cut out between N and L, to make room for another piece of strong leather NR (fig. 9.) which composes the valve. The circular part of this valve is broader than the hole in the middle of fig. 10. but not quite so broad as to fill up the inside of the ring of leather OQP of this fig. which is the same with GKI of fig. 10. The middle of this leather valve is strengthened by two brass (not iron) plates, the uppermost of which is seen at R of fig. 9: the one on its underside is a little smaller than the hole in the valve-plate, that it may go freely in; and the upper plate R is larger than this hole, that it may compress the leather to its brim all round. It is evident, that when this plate with its leathers is put between the joint flanches, and all is screwed together, the tail of leather N of fig. 9. will be compressed between the plates, and form a hinge, on which the valve can turn, rising and falling. There is a similar valve fastened to the upper side, or broadest base of the piston. This description serves for both valves, and in general for most valves which are to be found in any parts of a pump.

19.
Its mode
of opera-
tion.

The reader will now understand, without any repetition, the process of the whole operation of a sucking-pump. The piston rarefies the air in the working barrel, and that in the suction-pipe expands thro' the valve into the barrel; and, being no longer a balance for the atmospheric pressure, the water rises into the suction-pipe; another stroke of the piston produces a similar effect, and the water rises farther, but by a smaller step than by the preceding stroke: by repeating the strokes of the piston, the water gets into the barrel; and when the piston is now pushed down through it, it gets

Pump

above the piston, and must now be lifted up to any height. The suction-pipe is commonly of smaller size than the working barrel, for the sake of economy. It is not necessary that it be so wide: but it may be, and often is, made too small. It should be of such a size, that the pressure of the atmosphere may be able to fill the barrel with water as fast as the piston rises. If a void is left below the piston, it is evident that the piston must be carrying the whole weight of the atmosphere, besides the water which is lying above it. Nay, if the pipe be only so wide, that the barrel shall fill precisely as fast as the piston rises, it must sustain all this pressure. The suction-pipe should be wider than this, that all the pressure of the atmosphere which exceeds the weight of the pillar in the suction-pipe may be employed in pressing it on the under surface of the piston, and thus diminish the load. It cannot be made too wide; and too strict an economy in this respect may very sensibly diminish the performance of the pump, and more than defeat its own purpose. This is most likely when the suction-pipe is long, because there the length of the pillar of water nearly balances the air's pressure, and leaves very little accelerating force; so that water will rise but slowly even in the widest pipe. All these things will be made the subjects of computation afterwards.

It is plain that there will be limitations to the rise of the water in the suction-pipe, similar to what we found when the whole pump was an uniform cylinder. Let a be the height of the fixed valve above the water in the cistern: let B and b be the spaces in cubic measure between this valve and the piston in its highest and lowest positions, and therefore express the bulks of the air which may occupy these spaces: let y be the distance between the fixed valve and the water in the suction-pipe, when it has attained its greatest height by the rarefaction of the air above it: let h be the height of a column of water in equilibrio, with the whole pressure of the atmosphere, and therefore having its weight in equilibrio with the elasticity of common air: and let x be the height of the column whose weight balances the elasticity of the air in the suction-pipe, when rarefied as much as it can be by the action of the piston, the water standing at the height $a-y$.

Then, because this elasticity, together with the column $a-y$ in the suction-pipe, must balance the whole pressure of the atmosphere, (see PNEUMATICS. n° 108.), we must have $b = x + a-y$, and $y = a + x-b$.

When the piston was in its lowest position, the bulk of the air between it and the fixed valve was b . Suppose the valve kept shut, and the piston raised to its highest position, the bulk will be B , and its density $\frac{b}{B}$, and its elasticity, or the height of the column whose weight will balance it, will be $b \frac{b}{B}$. If the air in the suction-pipe be denser than this, and consequently more elastic, it will lift the valve, and some will come in; therefore, when the pump has rarefied the air as much as it can, so that none does, in fact, come in, the elasticity of the air in the suction-pipe must be the same.

Therefore $x = b \frac{b}{B}$:

We

Pump. We had $y = a + x - b$. Therefore $y = a + b \frac{b}{B} - b = a + \frac{b-b}{B} b = a - \frac{B-b}{B} b$.

Therefore when $\frac{B-b}{B} b$ is less than a , the water will stop before it reaches the fixed valve. But when a is less than $\frac{B-b}{B} b$, the water will get above the fixed valve, y becoming negative.

But it does not follow that the water will reach the piston, that is, will rise so high that the piston will pass through it in its descent. Things now come into the condition of a pump of uniform dimensions from top to bottom; and this point will be determined by what was said when treating of such a pump.

²⁰ The same pump is used in an inverted position; There is another form of the sucking pump which is much used in great water works, and is of equal efficacy with the one now described. It is indeed the same pump in an inverted position. It is represented in fig. 11. where ABCD is the working barrel, immersed, with its mouth downwards, in the water of the cistern. It is joined by means of flanges to the rising pipe or MAIN.

This usually consists of two parts. The first, BEFC, is bent to one side, that it may give room for the iron frames TXYV, which carries the rod NO of the piston M, attached to the traverses RS, TOV of this frame. The other part, EGHF, is usually of a less diameter, and is continued to the place of delivery. The piston frame XTVY hangs by the rod Z, at the arm of a lever or working beam, not brought into the figure. The piston is perforated like the former, and is surrounded like it with a band of leather in form of a taper-dish. It has a valve K on its broad or upper base, opening when pressed from below. The upper end of the working barrel is pierced with a hole, covered with a valve I, also opening upwards.

Now suppose this apparatus immersed into the cistern till the water is above it, as marked by the line 2, 3, and the piston drawn up till it touch the end of the barrel. When the piston is allowed to descend by its own weight, the water rises up through its valve K, and fills the barrel. If the piston be now drawn up by the moving power of the machinery with which it is connected, the valve K shuts, and the piston pushes the water before it through the valve I into the main pipe EFGH. When the piston is again let down, the valve I shuts by its own weight and the pressure of the water incumbent on it, and the barrel is again filled by the water of the cistern. Drawing up the piston pushes this water into the main pipe, &c. and then the water is at length delivered at the place required.

²¹ And is called a lifting pump. This pump is usually called the *lifting pump*; perhaps the simplest of all in its principle and operation.—It needs no farther explanation: and we proceed to describe

²² Forcing-pump described. The FORCING PUMP, represented in fig. 12. It consists of a working barrel ABCD, a suction-pipe CDEF, and a main or rising pipe. This last is usually in three joints. The first GHKI may be considered as making part of the working barrel, and is commonly cast in one piece with it. The second IKLM is joined to it by flanges, and forms the elbow which this

pipe must generally have. The third LNOM is properly the beginning of the main, and is continued to the place of delivery. At the joint IK there is a hanging valve or clack S; and there is a valve R on the top of the suction-pipe.

The piston PQTV is solid, and is fastened to a stout iron rod which goes through it, and is fixed by a key drawn through its end. The body of the piston is a sort of double cone, widening from the middle to each end, and is covered with two bands of very strong leather, fitted to it in the manner already described.

²³ Its mode of operation. The operation of this pump is abundantly simple. When the piston is thrust into the pump, it pushes the air before it through the valve S, for the valve R remains shut by its own weight. When it has reached near the bottom, and is drawn up again, the air which filled the small space between the piston and the valve S now expands into the barrel; for as soon as the air begins to expand, it ceases to balance the pressure of the atmosphere, which therefore shuts the valve S. By the expansion of the air in the barrel the equilibrium at the valve R is destroyed, and the air in the suction-pipe lifts the valve, and expands into the barrel; consequently it ceases to be a balance for the pressure of the atmosphere, and the water is forced into the suction-pipe. Pushing the piston down again forces the air in the barrel through the valve S, the valve R in the mean time shutting. When the piston is again drawn up, S shuts, R opens, the air in the suction-pipe dilates anew, and the water rises higher in it. Repeating these operations, the water gets at last into the working barrel, and is forced into the main by pushing down the piston, and is pushed along to the place of delivery.

²⁴ Is two-fold. The operation of this pump is therefore two-fold, sucking and forcing. In the first operation, the same force must be employed as in the sucking-pump, namely, a force equal to the weight of a column of water having the section of the piston for its base, and the height of the piston above the water in the cistern for its height. It is for the sake of this part of the operation that the upper cone is added to the piston. The air and water would pass by the sides of the lower cone while the piston is drawn up; but the leather of the upper cone applies to the surface of the barrel, and prevents this. The space contained between the barrel and the valve S is a great obstruction to this part of the operation, because this air cannot be rarified to a very great degree. For this reason the suction-pipe of a forcing-pump must not be made long. It is not indeed necessary; for by placing the pump a few feet lower, the water will rise into it without difficulty, and the labour of suction is as much diminished as that of impulsion is increased. However, an intelligent artist will always endeavour to make this space between the valve S and the lowest place of the piston as small as possible.

The power employed in forcing must evidently surmount the pressure of the whole water in the rising pipe, and (independent of what is necessary for giving the water the required velocity, so that the proper quantity per hour may be delivered), the piston has to withstand a force equal to the weight of a column of water having the section of the piston for its base, and the perpendicular altitude of the place of delivery above the lower surface of the piston for its height. It is quite

Pump.

quite indifferent in this respect what is the diameter of the rising pipe; because the pressure on the piston depends on the altitude of the water only, independent of its quantity. We shall even see that a small rising pipe will require a greater force to convey the water along it to any given height or distance.

When we would employ a pump to raise water in a crooked pipe, or in any pipe of moderate dimensions, this form of pump, or something equivalent, must be used. In bringing up great quantities of water from mines, the common sucking-pump is generally employed, as really the best of them all: but it is the most expensive, because it requires the pipe to be perpendicular, straight, and of great dimensions, that it may contain the piston rods. But this is impracticable when the pipe is crooked.

If the forcing pump, constructed in the manner now described, be employed, we cannot use forces with long rods. These would bend when pushed down by their further extremity. In this case, it is usual to employ only a short and stiff rod, and to hang it by a chain, and load it with a weight superior to the weight of water to be raised by it. The machinery therefore is employed, not in forcing the water along the rising-pipe, but in raising the weight which is to produce this effect by its subsequent descent.

In this case, it would be much better to employ the lifting-pump of fig. 11. For as the load on the forcers must be greater than the resistances which it must surmount, the force exerted by the machine must in like manner be greater than this load. This double excess would be avoided by using the lifting-pump.

25
Measure of
the quantity
of water
delivered
by any
pump.

It will readily occur to the reader that the quantity of water delivered by any pump will be in the joint proportion of the surface or base of the piston and its velocity: for this measures the capacity of that part of the working barrel which the piston passes over. The velocity of the water in the conduit pipe, and in its passage through every valve, will be greater or less than the velocity of the piston in the same proportion that the area of the piston or working-barrel is greater or less than the area of the conduit or valve. For whatever quantity of water passes through any section of the working-barrel in a second, the same quantity must go through any one of these passages. This enables us to modify the velocity of the water as we please: we can increase it to any degree at the place of delivery by diminishing the aperture through which it passes, provided we apply sufficient force to the piston.

26
The operation
of
pumps not
equable;

It is evident that the operation of a pump is by starts, and that the water in the main remains at rest, pressing on the valve during the time that the piston is withdrawn from the bottom of the working barrel. It is in most cases desirable to have this motion equable, and in some cases it is absolutely necessary. Thus, in the engine for extinguishing fires, the spout of water going by jerks could never be directed with a certain aim, and half of the water would be lost by the way; because a body at rest cannot in an instant be put in rapid motion, and the first portion of every jerk of water would have but a small velocity. A very ingenious contrivance has been fallen upon for obviating this inconvenience, and procuring a stream nearly equable. We have not been able to discover the author. At any

27
And the
mode of
making
them so.

convenient part of the rising pipe beyond the valve S there is annexed a capacious vessel VZ (fig. 13. n° 1 and 2.) close atop, and of great strength. When the water is forced along this pipe, part of it gets into this vessel, keeping the air confined above it, and it fills it to such a height V, that the elasticity of the confined air balances a column reaching to T, we shall suppose, in the rising pipe. The next stroke of the piston sends forward more water, which would fill the rising pipe to some height above T. But the pressure of this additional column causes some more of it to go into the air vessel, and compresses its air so much more that its elasticity now balances a longer column. Every succeeding stroke of the piston produces a like effect. The water rises higher in the main pipe, but some more of it goes into the air-vessel. At last the water appears at the place of delivery; and the air in the air-vessel is now so much compressed that its elasticity balances the pressure of the whole column. The next stroke of the piston sends forward some more water. If the diameter of the orifice of the main be sufficient to let the water flow out with a velocity equal to that of the piston, it will so flow out, rising no higher, and producing no sensible addition to the compression in the air-vessel. But if the orifice of the main be contracted to half its dimensions, the water sent forward by the piston cannot flow out in the time of the stroke without a greater velocity, and therefore a greater force. Part of it, therefore, goes into the air-vessel, and increases the compression. When the piston has ended its stroke, and no more water comes forward, the compression of the air in the air-vessel being greater than what was sufficient to balance the pressure of the water in the main pipe, now forces out some of the water which is lying below it. This cannot return towards the pump, because the valve S is now shut. It therefore goes forward along the main, and produces an efflux during the time of the piston's rising in order to make another stroke. In order that this efflux may be very equable, the air-vessel must be very large. If it be small, the quantity of water that is discharged by it during the return of the piston makes so great a portion of its capacity, that the elasticity of the confined air is too much diminished by this enlargement of its bulk, and the rate of efflux must diminish accordingly. The capacity of the air-vessel should be so great that the change of bulk of the compressed air during the inaction of the piston may be inconsiderable. It must therefore be very strong.

It is pretty indifferent in what way this air-vessel is connected with the rising pipe. It may join it laterally, as in fig. 13. n° 1. and the main pipe go on without interruption; or it may be made to surround an interruption of the main pipe, as in fig. 13. n° 2. It may also be in any part of the main-pipe. If the sole effect intended by it is to produce an equable jet, as in ornamental water-works, it may be near the end of the main. This will require much less strength, because there remains but a short column of water to compress the air in it. But it is, on the whole, more advantageous to place it as near the pump as possible, that it may produce an equable motion in the whole main-pipe. This is of considerable advantage: when a column of water several hundred feet long is at rest in the main-pipe, and the piston at one end of it put at once into motion, even

Pump.

Pump. even with a moderate velocity, the strain on the pipe would be very great. Indeed if it were possible to put the piston instantaneously into motion with a finite velocity, the strain on the pipe, tending to burst it, would be next to infinite. But this seems impossible in nature; all changes of motion *which we observe* are gradual, because all impelling bodies have some elasticity or softness by which they yield to compression. And, in the way in which pistons are commonly moved, *viz.* by cranks, or something analogous to them, the motion is *very sensibly* gradual. But still the air-vessel tends to make the motion along the main-pipe less defultory, and therefore diminishes those strains which would really take place in the main-pipe. It acts like the springs of a travelling carriage, whose jolts are incomparably less than those of a cart; and by this means really enables a given force to propel a greater quantity of water in the same time.

28
The defultory motion of the pistons

29
Corrected.

We may here by the way observe, that the attempts of mechanicians to correct this unequal motion of the piston-rod are misplaced, and if it could be done, would greatly hurt a pump. One of the best methods of producing this effect is to make the piston-rod consist of two parallel bars, having teeth in the sides which front each other. Let a toothed wheel be placed between them, having only the half of its circumference furnished with teeth. It is evident, without any farther description, that if this wheel be turned uniformly round its axis, the piston-rod will be moved uniformly up and down without intermission. This has often been put in practice; but the machine always went by jolts, and seldom lasted a few days. Unskilled mechanicians attributed this to defect in the execution: but the fault is essential, and lies in the principle.

30
But on a wrong principle.

The machine could not perform one stroke, if the first mover did not slacken a little, or the different parts of the machine did not yield by bending or by compression; and no strength of materials could withstand the violence of the strains at every reciprocation of the motion. This is chiefly experienced in great works which are put in motion by a water-wheel, or some other equal power exerted on the mass of matter of which the machine consists. The water-wheel being of great weight, moves with considerable steadiness or uniformity; and when an additional resistance is opposed to it by the beginning of a new stroke of the piston, its great quantity of motion is but little affected by this addition, and it proceeds very little retarded; and the machine must either yield a little by bending and compression, or go to pieces, which is the common event. Cranks are free from this inconvenience, because they accelerate the piston gradually, and bring it gradually to rest, while the water-wheel moves round with almost perfect uniformity. The only inconvenience (and it may be considerable) attending this slow motion of the piston at the beginning of its stroke is, that the valves do not shut with rapidity, so that some water gets back through them. But when they are properly formed and loaded, this is but trifling.

31
These equable pumps deliver very little more water than the others.

We must not imagine, that because the stream produced by the assistance of an air-barrel is almost perfectly equable, and because as much water runs out during the returning of the piston as during its active stroke, it therefore doubles the quantity of water. No more water can run out than what is sent forward by

the piston during its effective stroke. The continued stream is produced only by preventing the whole of this water from being discharged during this time, and by providing a propelling force to act during the piston's return. Nor does it enable the moving force of the piston to produce a double effect: for the compression which is produced in the air-vessel, more than what is necessary for merely balancing the quiescent column of water, reacts on the piston, resisting its compression just as much as the column of water would do which produces a velocity equal to that of the efflux. Thus if the water is made to spout with the velocity of eight feet per second, this would require an additional column of one foot high, and this would just balance the compression in the air-vessel, which maintains this velocity during the non-action of the piston. It is, however, a matter of fact, that a pump furnished with an air-vessel delivers a little more water than it would do without it. But the difference depends on the combination of many very dissimilar circumstances, which it is extremely difficult to bring into calculation. Some of these will be mentioned afterwards.

To describe, or even to enumerate, the immense variety of combinations of these three simple pumps would fill a volume. We shall select a few, which are more deserving of notice.

I. The common sucking-pump may, by a small addition, be converted into a lifting-pump, fitted for propelling the water to any distance, and with any velocity.

32
The sucking pump converted into a lifting pump.

Fig. 14. is a sucking-pump, whose working-barrel ACDB has a lateral pipe AEGHF connected with it close to the top. This terminates in a *main* or rising pipe IK, furnished or not with a valve L. The top of the barrel is shut up by a strong plate MN, having a hollow neck terminating in a small flanch. The piston rod QR passes through this neck, and is nicely turned and polished. A number of rings of leather are put over the rod, and strongly compressed round it by another flanch and several screwed bolts, as is represented at OP. By this contrivance the rod is closely grasped by the leathers, but may be easily drawn up and down, while all passage of air or water is effectually prevented.

The piston S is perforated, and furnished with a valve opening upwards. There is also a valve T on the top of the suction-pipe YX; and it will be of advantage, though not absolutely necessary, to put a valve L at the bottom of the rising pipe. Now suppose the piston at the bottom of the working-barrel. When it is drawn up, it tends to compress the air above it, because the valve in the piston remains shut by its own weight. The air therefore is driven through the valve L into the rising pipe, and escapes. In the mean time, the air which occupied the small space between the piston and the valve T expands into the upper part of the working barrel; and its elasticity is so much diminished thereby, that the atmosphere presses the water of the cistern into the suction-pipe, where it will rise till an equilibrium is again produced. The next downward stroke of the piston allows the air, which had come from the suction-pipe into the barrel during the ascent of the piston, to get through its valve. Upon drawing up the piston, this air is also drawn off through the rising pipe. Repeating this process brings the wa-

Pump.
33
Advantages of this conversion.

ter at last into the working-barrel, and it is then driven along the rising-pipe by the piston.

This is one of the best forms of a pump. The rarefaction may be very perfect, because the piston can be brought so near to the bottom of the working-barrel: and, for forcing water in opposition to great pressures, it appears preferable to the common forcing-pump; because in that the piston rods are compressed and exposed to bending, which greatly hurts the pump by wearing the piston and barrel on one side. This soon renders it less tight, and much water squirts out by the sides of the piston. But in this pump the piston rod is always drawn or pulled, which keeps it straight; and rods exert a much greater force in opposition to a pull than in opposition to compression. The collar of leather round the piston-rods is found by experience to need very little repairs, and is very impervious to water. The whole is very accessible for repairs; and in this respect much preferable to the common pump in deep mines, where every fault of the piston obliges us to draw up some hundred feet of piston-rods. By this addition, too, any common pump for the service of a house is converted into an engine for extinguishing fire, or may be made to convey the water to every part of the house; and this without hurting or obstructing its common uses. All that is necessary is to have a large cock on the upper part of the working-barrel opposite to the lateral pipe in this figure. This cock serves for a spout when the pump is used for common purposes; and the merely shutting this cock converts the whole into an engine for extinguishing fire or for supplying distant places with water. It is scarcely necessary to add, that for these services it will be proper to connect an air-vessel with some convenient part of the rising pipe, in order that the current of the water may be continual.

34
Equable streams produced in great works by combinations.

We have frequently spoken of the advantages of a continued current in the main pipe. In all great works a considerable degree of uniformity is produced by the manner of disposing the actions of the different pumps; for it is very rarely that a machine works but one pump. In order to maintain some uniformity in the resistance, that it may not all be opposed at once to the moving power, with intervals of total inaction, which would produce a very hobbling motion, it is usual to distribute the work into portions, which succeed alternately; and thus both diminish the strain, and give greater uniformity of action, and frequently enable a natural power which we can command, to perform a piece of work, which would be impossible if the whole resistance were opposed at once. In all pump machines therefore we are obviously directed to construct them so that they may give motion to at least two pumps, which work alternately. By this means a much greater uniformity of current is produced in the main pipe. It will be rendered still more uniform if four are employed, succeeding each other at the interval of one quarter of the time of a complete stroke.

35
A single pump for this purpose described.

But ingenious men have attempted the same thing with a single pump, and many different constructions for this purpose have been proposed and executed. The thing is not of much importance, nor of great research. We shall content ourselves therefore with the description of one that appears to us the most perfect, both in respect of simplicity and effect.

11. It consists of a working-barrel AB (fig. 15.) close at both ends. The piston C is solid, and the rod OP passes through a collar of leathers in the plate, which closes the upper end of the working-barrel. This barrel communicates laterally with two pipes H, K; the communication *m* and *n* being as near to the top and bottom of the barrel as possible. Adjoining to the passage *m* are two valves F and G opening upwards. Similar valves accompany the passage *n*. The two pipes H and K unite in a larger rising pipe L. They are all represented as in the same plane; but the upper ends must be bent backwards, to give room for the motion of the piston-rod OP.

Suppose the piston close to the entry of the lateral pipe *n*, and that it is drawn up: it compresses the air above it, and drives it through the valve G, where it escapes along the rising pipe; at the same time it rarefies the air in the space below it. Therefore the weight of the atmosphere shuts the valve E, and causes the water of the cistern to rise through the valve D, and fill the lower part of the pump. When the piston is pushed down again, this water is first driven through the valve E, because D immediately shuts; and then most of the air which was in this part of the pump at the beginning goes up through it, some of the water coming back in its stead. In the mean time, the air which remained in the upper part of the pump after the ascent of the piston is rarefied by its descent; because the valve G shuts as soon as the piston begins to descend, the valve F opens, the air in this suction pipe Ff expands into the barrel, and the water rises into the pipes by the pressure of the atmosphere. The next rise of the piston must bring more water into the lower part of the barrel, and must drive a little more air through the valve G, namely, part of that which had come out of the suction-pipe Ff; and the next descent of the piston must drive more water into the rising pipe H, and along with it most if not all of the air which remained below the piston, and must rarefy still more the air remaining above the piston; and more water will come in through the pipe Ff, and get into the barrel. It is evident that a few repetitions will at last fill the barrel on both sides of the piston with water. When this is accomplished, there is no difficulty in perceiving how, at every rise of the piston, the water of the cistern will come in by the valve D, and the water in the upper part of the barrel will be driven thro' the valve G; and, in every descent of the piston, the water of the cistern will come into the barrel by the valve F, and the water below the piston will be driven through the valve E: and thus there will be a continual influx into the barrel through the valves D and F, and a continual discharge along the rising pipe L through the valves E and G.

This machine is, to be sure, equivalent to two forcing pumps, although it has but one barrel and one piston; but it has no sort of superiority. It is not even more economical in most cases; because we apprehend that the additional workmanship will fully compensate for the saving in the rest of the machinery, because one lever produces both motions. We cannot therefore say that it is inferior to two pumps; and we acknowledge that there is some ingenuity in the contrivance.

We recommend to our readers the perusal of Belidor's

Pump.

36
It is equivalent to two forcing pumps.

Pump.

Authors
recom-
mended.

dor's *Architecturæ Hydraulicæ*, where is to be found a great variety of combinations and forms of the simple pumps; but we must caution them with respect to his theories, which in this article are extremely defective. Also in Leupold's *Theatrum Machinarum Hydraulicarum*, there is a prodigious variety of all kinds of pumps, many of them very singular and ingenious, and many which have particular advantages, which may suit local circumstances, and give them a preference. But it would be improper to swell a work of this kind with so many peculiarities; and a person who makes himself master of the principles delivered here in sufficient detail, can be at no loss to suit a pump to his particular views, or to judge of the merit of such as may be proposed to him.

We must now take notice of some very considerable and important varieties in the form and contrivance of the essential parts of a pump.

ccccxv.

III. The forcing pump is sometimes of a very different form from that already described. Instead of a piston, which applies itself to the inside of the barrel, and slides up and down in it, there is a long cylinder POQ (fig. 16.) nicely turned and polished on the outside, and of a diameter somewhat less than the inside of the barrel. This cylinder (called a *PLUNGER*) slides through a collar of leathers on the top of the working barrel, and is constructed as follows. The top of the barrel terminates in a flanch *ab*, pierced with four holes for receiving screw-bolts. There are two rings of metal, *c d, e f*, of the same diameter, and having holes corresponding to those in the flanch. Four rings of soft leather, of the same size, and similarly pierced with holes, are well soaked in a mixture of oil, tallow, and a little rosin. Two of these leather rings are laid on the pump flanch, and one of the metal rings above them. The plunger is then thrust down through them, by which it turns their inner edges downwards. The other two rings are then slipped on at the top of the plunger, and the second metal ring is put over them, and then the whole are slid down to the metal ring. By this the inner edges of the last leather rings are turned upwards. The three metal rings are now forced together by the screwed bolts; and thus the leathern rings are strongly compressed between them, and made to grasp the plunger so closely that no pressure can force the water through between. The upper metal ring just allows the plunger to pass through it, but without any play; so that the turned up edges, of the leathern rings do not come up between the plunger and the upper metal ring, but are lodged in a little conical taper, which is given to the inner edge of the upper plate, its hole being wider below than above. It is on this trifling circumstance that the great tightness of the collar depends. To prevent the leathers from shrinking by drought, there is usually a little cistern formed round the head of the pump, and kept full of water. The plunger is either forced down by a rod from a working beam, or by a set of metal-weights laid on it, as is represented in the figure.

39
Its mode of
operation.

It is hardly necessary to be particular in explaining the operation of this pump. When the plunger is at the bottom of the barrel, touching the fixed valve M with its lower extremity, it almost completely fills it. That it may do it completely, there is sometimes a small pipe RSZ branching out from the top of the barrel,
VOL. XV.

and fitted with a cock at S. Water is admitted till the barrel is completely filled, and the cock is then shut. Now when the plunger is drawn up, the valve N in the rising pipe must remain shut by the pressure of the atmosphere, and a void must be made in the barrel. Therefore the valve M on the top of the suction-pipe must be opened by the elasticity of the air in this pipe, and the air must expand into the barrel; and, being no longer a balance for the atmosphere, the water in the cistern must be forced into the suction-pipe, and rise in it to a certain height. When the plunger descends, it must drive the water through the valve N (for the valve M will immediately shut), and along with it most of the air which had come into the barrel. And as this air occupied the upper part of the barrel, part of it will remain when the plunger has reached the bottom; but a stroke or two will expel it all, and then every succeeding stroke of the descending piston will drive the water along the rising pipe, and every ascent of the plunger will be followed by the water from the cistern.

The advantage proposed by this form of piston is, that it may be more accurately made and polished than the inside of a working barrel, and it is of much easier repair. Yet we do not find that it is much used, although an invention of last century (we think by Sir Samuel Morland), and much praised by the writers on these subjects.

It is easy to see that the sucking-pump may be varied in the same way. Suppose this plunger to be open both at top and bottom, but the bottom filled with a valve opening upward. When this is pushed to the bottom of the barrel, the air which it tends to compress lifts the valve (the lateral pipe FIK being taken away and the passage shut up), and escapes through the plunger. When it is drawn up, it makes the same rarefaction as the solid plunger, because the valve at O shuts, and the water will come up from the cistern as in the former case. If the plunger be now thrust down again, the valve M shuts, the valve O is forced open, and the plunger is filled with water. This will be lifted by it during its next ascent; and when it is pushed down again, the water which filled it must now be pushed out, and will flow over its sides into the cistern at the head of the barrel. Instead of making the valve at the bottom of the piston, it may be made at the top; but this disposition is much inferior, because it cannot rarefy the air in the barrel one half. This is evident; for the capacity of the barrel and plunger together cannot be twice the capacity of the barrel.

40
Sucking-
pump simi-
larly va-
ried.

IV. It may be made after a still different form, as represented in fig. 17. Here the suction-pipe CO comes up through a cistern KMNL deeper or longer than the intended stroke of the piston, and has a valve C at top. The piston, or what acts in lieu of it, is a tube AHGB, open at both ends, and of a diameter somewhat larger than that of the suction-pipe. The interval between them is filled up at HG by a ring or belt of soft leather, which is fastened to the outer tube, and moves up and down with it sliding along the smoothly polished surface of the suction-pipe with very little friction. There is a valve I on the top of this piston, opening upwards. Water is poured into the outer cistern.

41
Another
form of the
sucking-
pump.

The outer cylinder or piston being drawn up from the bottom, there is a great rarefaction of the air which

42
And its
mode of
operation.

Pump. was between them, and the atmosphere presses the water up through the suction-pipe to a certain height; for the valve I keeps shut by the pressure of the atmosphere and its own weight. Pushing down the piston causes the air, which had expanded from the suction-pipe into the piston, to escape through the valve I; drawing it up a second time, allows the atmosphere to press more water into the suction-pipe, to fill it, and also part of the piston. When this is pushed down again, the water which had come through the valve C is now forced out through the valve I into the cistern KMNL, and now the whole is full of water. When, therefore, the piston is drawn up, the water follows, and fills it, if not 33 feet above the water in the cistern; and when it is pushed down again, the water which filled the piston is all thrown out into the cistern; and after this it delivers its full contents of water every stroke. The water in the cistern KMNL effectually prevents the entry of any air between the two pipes; so that a very moderate compression of the belt of soft leather at the mouth of the piston cylinder is sufficient to make all perfectly tight.

43
The piston
cylinder
differently
formed.

It might be made differently. The ring of leather might be fastened round the top of the inner cylinder at DE, and slide on the inside of the piston cylinder; but the first form is most easily executed. Muschenbroeck has given a figure of this pump in his large system of natural philosophy, and speaks very highly of its performance. But we do not see any advantage which it possesses over the common sucking-pump. He indeed says that it is without friction, and makes no mention of the ring of leather between the two cylinders. Such a pump will raise water extremely well to a small height, and it seems to have been a model only which he had examined: But if the suction-pipe is long, it will by no means do without the leather; for on drawing up the piston, the water of the upper cistern will rise between the piston, and fill the piston, and none will come up through the suction-pipe.

44
Pumps
without
friction
not of im-
portant
use.

We may take this opportunity of observing, that the many ingenious contrivances of pumps without friction are of little importance in great works; because the friction which is completely sufficient to prevent all escape of water in a well-constructed pump is but a very trifling part of the whole force. In the great pumps which are used in mines, and are worked by a steam-engine, it is very usual to make the pistons and valves without any leather whatever. The working barrel is bored truly cylindrical, and the piston is made of metal of a size that will just pass along it without sticking. When this is drawn up with the velocity competent to a properly loaded machine, the quantity of water which escapes round the piston is insignificant. The piston is made without leathers, not to avoid friction, which is also insignificant in such works; but to avoid the necessity of frequently drawing it up for repairs through such a length of pipes.

45
Example
of a simple
pump
without
friction.

V. If a pump absolutely without friction is wanted, the following seems preferable for simplicity and performance to any we have seen, when made use of in proper situations. Let NO (fig. 18.) be the surface of the water in the pit, and K the place of delivery. The pit must be as deep in water as from K to NO. ABCD is a wooden trunk, round or square, open at both ends, and having a valve P at the bottom. The

top of this trunk must be on a level with K, and has a small cistern EADF. It also communicates laterally with a rising pipe GHK, furnished with a valve at H opening upwards. LM is a beam of timber so fitted to the trunk as to fill it without sticking, and is of at least equal length. It hangs by a chain from a working beam, and is loaded on the top with weights exceeding that of the column of water which it displaces. Now suppose this beam allowed to descend from the position in which it is drawn in the figure; the water must rise all around it, in the crevice which is between it and the trunk, and also in the rising pipe; because the valve P shuts, and H opens; so that when the plunger has got to the bottom, the water will stand at the level of K. When the plunger is again drawn up to the top by the action of the moving power, the water sinks again in the trunk, but not in the rising pipe, because it is stopped by the valve H. Then allowing the plunger to descend again, the water must again rise in the trunk to the level of K, and it must now flow out at K; and the quantity discharged will be equal to the part of the beam below the surface of the pit-water, deducting the quantity which fills the small space between the beam and the trunk. This quantity may be reduced almost to nothing; for if the inside of the trunk and the outside of the beam be made tapering, the beam may be let down till they exactly fit; and as this may be done in square work, a good workman can make it exceedingly accurate. But in this case, the lower half of the beam and trunk must not taper; and this part of the trunk must be of sufficient width round the beam to allow free passage into the rising pipe. Or, which is better, the rising pipe must branch off from the bottom of the trunk. A discharge may be made from the cistern EADF, so that as little water as possible may descend along the trunk when the piston is raised.

One great excellence of this pump is, that it is perfectly free from all the deficiencies which in common pumps result from want of being air-tight. Another is, that the quantity of water raised is precisely equal to the power expended; for any want of accuracy in the work, while it occasions a diminution of the quantity of water discharged, makes an equal diminution in the weight which is necessary for pushing down the plunger. We have seen a machine consisting of two such pumps suspended from the arms of a long beam, the upper side of which was formed into a walk with a rail on each side. A man stood on one end till it got to the bottom, and then walked soberly up to the other end, the inclination being about twenty-five degrees at first, but gradually diminished as he went along, and changed the load of the beam. By this means he made the other end go to the bottom, and so on alternately, with the easiest of all exertions, and what we are most fitted for by our structure. With this machine, a very feeble old man, weighing 110 pounds, raised 7 cubic feet of water 11½ feet high in a minute, and continued working 8 or 10 hours every day. A stout young man, weighing nearly 135 pounds, raised 8½ to the same height; and when he carried 30 pounds, conveniently slung about him, he raised 9½ feet to this height, working 10 hours a-day without fatiguing himself. This exceeds Desagulier's maximum of a hoghead of water 10 feet high in a minute, in the proportion

tion.

portion of 9 to 7 nearly. It is limited to very moderate heights; but in such situations it is very effectual. It was the contrivance of an untaught labouring man, possessed of uncommon mechanical genius. We shall have occasion to mention, with respect, some other contrivances of the same person in the article *WATER-Works*.

VI. The most ingenious contrivance of a pump without friction is that of Mr Haskins, described by Desaguliers, and called by him the *QUICKSILVER PUMP*. Its construction and mode of operation are pretty complicated; but the following preliminary observations will, we hope, render it abundantly plain.

Let $ilmk$ (fig. 19.) be a cylindrical iron pipe, about six feet long, open at top. Let $egbf$ be another cylinder, connected with it at the bottom, and of smaller diameter. It may either be solid, or, if hollow, it must be close at top. Let $acdb$ be a third iron cylinder, of an intermediate diameter, so that it may move up and down between the other two without touching either, but with as little interval as possible. Let this middle cylinder communicate by means of the pipe AB , with the upright pipe FE , having valves C and D (both opening upwards) adjoining to the pipe of communication. Suppose the outer cylinder suspended by chains from the end of a working beam, and let mercury be poured into the interval between the three cylinders till it fills the space to op , about $\frac{1}{4}$ of their height. Also suppose that the lower end of the pipe FE is immersed into a cistern of water, and that the valve D is less than 33 feet above the surface of this water.

Now suppose a perforation made somewhere in the pipe AB , and a communication made with an air-pump. When the air-pump is worked, the air contained in CE , in AB , and in the space between the inner and middle cylinders, is rarefied, and is abstracted by the air-pump; for the valve D immediately shuts. The pressure of the atmosphere will cause the water to rise in the pipe CE , and will cause the mercury to rise between the inner and middle cylinders, and sink between the outer and middle cylinders. Let us suppose mercury 12 times heavier than water: Then for every foot that the water rises in EC , the level between the outside and inside mercury will vary an inch; and if we suppose DE to be 30 feet, then if we can rarefy the air so as to raise the water to D , the outside mercury will be depressed to q, r , and the inside mercury will have risen to s, t, sq and tr being about 30 inches. In this state of things, the water will run over by the pipe BA , and every thing will remain nearly in this position. The columns of water and mercury balance each other, and balance the pressure of the atmosphere.

While things are in this state of equilibrium, if we allow the cylinders to descend a little, the water will rise in the pipe FE , which we may now consider as a suction-pipe; for by this motion the capacity of the whole is enlarged, and therefore the pressure of the atmosphere will still keep it full, and the situation of the mercury will again be such that all shall be in equilibrio. It will be a little lower in the inside space and higher in the outside.

Taking this view of things, we see clearly how the water is supported by the atmosphere at a very con-

siderable height. The apparatus is analogous to a syphon which has one leg filled with water and the other with mercury. But it was not necessary to employ an air-pump to fill it. Suppose it again empty, and all the valves shut by their own weight. Let the cylinders descend a little. The capacity of the spaces below the valve D is enlarged, and therefore the included air is rarefied, and some of the air in the pipe CE must diffuse itself into the space quitted by the inner cylinder. Therefore the atmosphere will press some water up the pipe FE , and some mercury into the inner space between the cylinders. When the cylinders are raised again, the air which came from the pipe CE would return into it again, but is prevented by the valve C .—Raising the cylinders to their former height would compress this air; it therefore lifts the valve D , and escapes. Another depression of the cylinders will have a similar effect. The water will rise higher in FC , and the mercury in the inner space; and then, after repeated strokes, the water will pass the valve C , and fill the whole apparatus, as the air-pump had caused it to do before.—The position of the cylinders, when things are in this situation, is represented in fig. 20, the outer and inner cylinders in their lowest position having descended about 30 inches. The mercury in the outer space stands at q, r , a little above the middle of the cylinders, and the mercury in the inner space is near the top t, s of the inner cylinder. Now let the cylinders be drawn up. The water above the mercury cannot get back again through the valve C , which shuts by its own weight. We therefore attempt to compress it; but the mercury yields, and descends in the inner space, and rises in the outer till both are quickly on a level, about the height vv . If we continue to raise the cylinders, the compression forces out more mercury, and it now stands lower in the inner than in the outer space. But that there may be something to balance this inequality of the mercurial columns, the water goes through the valve D , and the equilibrium is restored when the height of the water in the pipe ED above the surface of the internal mercury is 12 times the difference of the mercurial columns (on the former supposition of specific gravity.) If the quantity of water is such as to rise two feet in the pipe ED , the mercury in the outer space will be two inches higher than that in the inner space. Another depression of the cylinders will again enlarge the space within the apparatus, the mercury will take the position of fig. 19. and more water will come in. Raising the cylinders will send this water four feet up the pipe ED , and the mercury will be four inches higher in the inner than in the outer space. Repeating this operation, the water will be raised still higher in DE ; and this will go on till the mercury in the outer space reaches the top of the cylinder; and this is the limit of the performance. The dimensions with which we set out will enable the machine to raise the water about 30 feet in the pipe ED ; which, added to the 30 feet of CF , makes the whole height above the pit-water 60 feet. By making the cylinders longer, we increase the height of FD . This machine must be worked with great attention, and but slowly; for at the beginning of the forcing stroke the mercury very rapidly sinks in the inner space and rises in the outer, and will dash out and be lost. To pre-

Pump.

Pump. vent this as much as possible, the outer cylinder terminates in a sort of cup or dish, and the inner cylinder should be tapered atop.

50 Ingenuity of the contrivance great The machine is exceedingly ingenious and refined; and there is no doubt but that its performance will exceed that of any other pump which raises the water to the same height, because friction is completely avoided, and there can be no want of tightness of the piston.

51 But the advantage trifling. But this is all its advantage; and, from what has been observed, it is but trifling. The expence would be enormous; for with whatever care the cylinders are made, the interval between the inner and outer cylinders must contain a very great quantity of mercury. The middle cylinder must be made of iron plate, and must be without a seam, for the mercury would dissolve every folder. For such reasons, it has never come into general use. But it would have been unpardonable to have omitted the description of an invention which is so original and ingenious; and there are some occasions where it may be of great use, as in nice experiments for illustrating the theory of hydraulics, it would give the finest pistons for measuring the pressures of water in pipes, &c. It is on precisely the same principle that the cylinder bellows, described in the article PNEUMATICS, are constructed.

52 Description of another pump without friction. We beg leave to conclude this part of the subject with the description of a pump without friction, which may be constructed in a variety of ways by any common carpenter, without the assistance of the pump-maker or plumber, and will be very effective for raising a great quantity of water to small heights, as in draining marshes, marble pits, quarries, &c. or even for the service of a house.

VII. ABCD (fig. 21.) is a square trunk of carpenter's work open at both ends, and having a little cistern and spout at top. Near the bottom there is a partition made of board, perforated with a hole E, and covered with a clack. *ffff* represents a long cylindrical bag or pudding, made of leather or of double canvas, with a fold of thin leather such as sheepskin between the canvas bags. This is firmly nailed to the board E with soft leather between. The upper end of this bag is fixed on a round board, having a hole and valve F. This board may be turned in the lathe with a groove round its edge, and the bag fastened to it by a cord bound tight round it. The fork of the piston-rod FG is firmly fixed into this board; the bag is kept distended by a number of wooden hoops or rings of strong wire *ff, ff, ff, &c.* put into it at a few inches distance from each other. It will be proper to connect these hoops before putting them in, by three or four cords from top to bottom, which will keep them at their proper distances. Thus will the bag have the form of a barber's bellows powder-puff. The distance between the hoops should be about twice the breadth of the rim of the wooden ring to which the upper valve and piston-rod are fixed.

53 A model of operation, &c. Now let this trunk be immersed in the water. It is evident that if the bag be stretched from the compressed form which its own weight will give it by drawing up the piston-rod, its capacity will be enlarged, the valve F will be shut by its own weight, the air in the bag will be rarefied, and the atmosphere will press the water into the bag. When the rod is thrust down again, this water will come out by the valve F, and fill part of the trunk. A repetition of the operation will have a similar effect; the trunk will be filled, and the water will at last be discharged by the spout.

Pump. Here is a pump without friction, and perfectly tight. For the leather between the folds of canvas renders the bag impervious both to air and water. And the canvas has very considerable strength. We know from experience that a bag of six inches diameter, made of sail-cloth n^o 3. with a sheep skin between, will bear a column of 15 feet of water, and stand six hours work per day for a month without failure, and that the pump is considerably superior in effect to a common pump of the same dimensions. We must only observe, that the length of the bag must be three times the intended length of the stroke; so that when the piston-rod is in its highest position, the angles or ridges of the bag may be pretty acute. If the bag be more stretched than this, the force which must be exerted by the labourer becomes much greater than the weight of the column of water which he is raising. If the pump be laid aslope, which is very usual in these occasional and hasty drawings, it is necessary to make a guide for the piston-rod within the trunk, that the bag may play up and down without rubbing on the sides, which would quickly wear it out.

The experienced reader will see that this pump is very like that of Cossët and De la Deuille, described by Belidor Vol. II. p. 120. and most writers on hydraulics. It would be still more like it, if the bag were on the under side of the partition E, and a valve placed farther down the trunk. But we think that our form is greatly preferable in point of strength. When in the other situation, the column of water lifted by the piston tends to burst the bag, and this with a great force, as the intelligent reader well knows. But in the form recommended here, the bag is compressed, and the strain on each part may be made much less than that which tends to burst a bag of six inches diameter. The nearer the rings are placed to each other the smaller will the strain be.

The same bag-piston may be employed for a forcing pump, by placing it below the partition, and inverting the valve; and it will then be equally strong, because the resistance in this case too will act by compression.

We now come naturally to the consideration of the different forms which may be given to the pistons and valves of a pump. A good deal of what we have been describing already is reducible to this head; but, having a more general appearance, changing as it were the whole form and the structure of the pump, it was not improper to keep these things together.

The great desideratum in a piston is, that it be as tight as possible, and have as little friction as is consistent with this indispensable quality. We have already said, that the common form, when carefully executed, has these properties in an eminent degree. And accordingly this form has kept its ground amidst all the improvements which ingenious artists have made. Mr Belidor, an author of the first reputation, has given the description of a piston which he highly extols, and is undoubtedly a very good one, constructed from principle, and extremely well composed.

54 Pistons should have little friction. It consists of a hollow cylinder of metal *g b* (fig. 22.) An improved one by Belidor. pierced with a number of holes, and having at top a flanch AB, whose diameter is nearly equal to that of the trunk.

55 the

⁵⁶ **Pump.** the working-barrel of the pump. This flanch has a groove round it. There is another flanch IK below, by which this hollow cylinder is fastened with bolts to the lower end of the piston, represented in fig. 23. This consists of a plate CD, with a grooved edge similar to AB, and an intermediate plate which forms the seat of the valve. The composition of this part is better understood by inspecting the figure than by any description. The piston-rod HL is fixed to the upper plate by bolts through its different branches at G, G. This metal body is then covered with a cylindrical bag of leather, fastened on it by cords bound round it, filling up the grooves in the upper and lower plates. The operation of the piston is as follows.

A little water is poured into the pump, which gets past the sides of the piston, and lodges below in the fixed valve. The piston being pushed down dips into this water, and it gets into it by the valve. But as the piston in descending compresses the air below it, this compressed air also gets into the inside of the piston, swells out the bag which furrounds it, and compresses it to the sides of the working-barrel. When the piston is drawn up again, it must remain tight, because the valve will shut and keep in the air in its most compressed state; therefore the piston must perform well during the suction. It must act equally well when pushed down again, and acting as a forcer; for however great the resistance may be, it will affect the air within the piston to the same degree, and keep the leather close applied to the barrel. There can be no doubt therefore of the piston's performing both its offices completely; but we imagine that the adhesion to the barrel will be greater than is necessary: it will extend over the whole surface of the piston, and be equally great in every part of its surface; and we suspect that the friction will therefore be very great. We have very high authority for supposing that the adhesion of a piston of the common form, carefully made, will be such as will make it perfectly tight; and it is evident that the adhesion of Belidor's piston will be much greater, and it will be productive of worse consequences. If the leather bag is worn through in any one place, the air escapes, and the piston ceases to be compressed altogether; whereas in the common piston there will very little harm result from the leather being worn through in one place, especially if it project a good way beyond the base of the cone. We still think the common piston preferable. Belidor's piston would do much better inverted as the piston of a sucking pump; and in this situation it would be equal, but not superior, to the common.

⁵⁷ **Another by the same author.** Belidor describes another forcing piston, which he had executed with success, and prefers to the common wooden forcer. It consists of a metal cylinder or cone, having a broad flanch united to it at one end, and a similar flanch which is screwed on the other end. Between these two plates are a number of rings of leather strongly compressed by the two flanches, and then turned in a lathe like a block of wood, till the whole fits tight, when dry, into the barrel. It will swell, says he, and soften with the water, and withstand the greatest pressures. We cannot help thinking this but an indifferent piston. When it wears, there is nothing to squeeze it to the barrel. It may indeed be taken out and another ring or two of leather put in, or the flanches may be more strongly screwed together: but all this

may be done with any kind of piston; and this has therefore no peculiar merit.

The following will, we presume, appear vastly preferable, ABCD (fig. 24.) is the solid wooden or metal block of the piston; EF is a metal plate, which is turned hollow or dish-like below, so as to receive within it the solid block. The piston rod goes through the whole, and has a shoulder above the plate EF, and a nut H below. Four screw-bolts, such as *i k, l m*, also go through the whole, having their heads *k, m* sunk into the block, and nuts above at *i, l*. The packing or stuffing, as it is termed by the workmen, is represented at NO. This is made as solid as possible, and generally consists of soft hempen twine well soaked in a mixture of oil, tallow, and rosin. The plate EF is gently screwed down, and the whole is then put into the barrel, fitting it as tight as may be thought proper. When it wears loose, it may be tightened at any time by screwing down the nuts *i l*, which cause the edges of the dish to squeeze out the packing, and compress it against the barrel to any degree.

⁶⁰ The greatest difficulty in the construction of a piston is to give a sufficient passage through it for the water, and yet allow a firm support for the valve, and fixture for the piston rod. We shall see presently that it occasions a considerable expence of the moving power to force a piston with a narrow perforation through the water lodged in the working barrel. When we are raising water to a small height, such as 10 or 20 feet, the power so expanded amounts to a fourth part of the whole, if the water-way in the piston is less than one-half of the section of the barrel, and the velocity of the piston two feet *per* second, which is very moderate. There can be no doubt, therefore, that metal pistons are preferable, because their greater strength allows much wider apertures.

⁶¹ The following piston, described and recommended by Belidor, seems as perfect in these respects as the nature of things will allow. We shall therefore describe it in the author's own words as a model, which may be adopted with confidence in the greatest works.

"The body of the piston is a truncated metal cone CCXX (fig. 25.) having a small fillet at the greater end. Fig. 26 shows the profile, and fig. 27. the plan of its upper base; where appears a cross bar DD, pierced with an oblong mortise E for receiving the tail of the piston-rod. A band of thick and uniform leather AA (fig. 26. and 28.) is put round this cone, and secured by a brass hoop BB firmly driven on its smaller end, where it is previously made thinner to give room for the hoop.

"This piston is covered with a leather valve, fortified with metal plates GG (fig. 29.) These plates are wider than the hole of the piston, so as to rest on its rim. There are similar plates below the leather of a smaller size, that they may go into the hollow of the piston; and the leather is firmly held between the metal plates by screws H, H, which go through all. This is represented by the dotted circle IK. Thus the pressure of the incumbent column of water is supported by the plates GG, whose circular edges rest on the brim of the water-way, and thus straight edges rest on the cross bar DD of fig. 26. and 27. This valve is laid on the top of the conical box in such a manner that its middle FF rests on the cross bar. To bind all together, the

⁵⁹ **Pump.** Another recommended as preferable.

⁶⁰ Difficulties in constructing pistons.

⁶¹ Considerably removed in one described by Belidor.

Plate CCCCXXXV

⁵⁸ **Objections to it.**

Pump. the end of the piston-rod is formed like a cross, and the arms MN (fig. 30.) are made to rest on the diameter FF of the valve, the tail EP going through the hole E in the middle of the leather, and through the mortise E of the cross bar of the box; and also through another bar QR (fig. 28. and 29.) which is notched into the lower brim of the box. A key V is then driven into the hole T in the piston-rod; and this wedges all fast. The bar QR is made strong; and its extremities project a little, so as to support the brass hoop BB which binds the leather band to the piston-box. The adjoining scale gives the dimensions of all the parts, as they were executed for a steam-engine near Condé, where the piston gave complete satisfaction."

62
Advantages of this piston.

This piston has every advantage of strength, tightness, and large water-way. The form of the valve (which has given it the name of the *butterfly-valve*) is extremely favourable to the passage of the water; and as it has but half the motion of a complete circular valve, less water goes back while it is shutting.

63
Another ingenious and useful piston described.

The following piston is also ingenious, and has a good deal of merit. OPPO (fig. 31.) is the box of the piston, having a perforation Q, covered above with a flat valve K, which rests in a metal plate that forms the top of the box. ABCBA is a stirrup of iron to which the box is fixed by screws *a, a, a, a*, whose heads are sunk in the wood. This stirrup is perforated at C, to receive the end of the piston-rod, and a nut H is screwed on below to keep it fast. DEFED is another stirrup, whose lower part at DD forms a hoop like the sole of a stirrup, which embraces a small part of the top of the wooden box. The lower end of the piston-rod is screwed; and before it is put into the holes of the two stirrups (through which holes it slides freely) a broad nut G is screwed on it. It is then put into the holes, and the nut H firmly screwed up. The packing RR is then wound about the piston as tight as possible till it completely fills the working barrel of the pump. When long use has rendered it in any degree loose, it may be tightened again by screwing down the nut G. This causes the ring DD to compress the packing between it and the projecting shoulder of the box at PP; and thus causes it to swell out, and apply itself closely to the barrel.

64
Another on a different principle.

We shall add only another form of a perforated piston; which being on a principle different from all the preceding, will suggest many others; each of which will have its peculiar advantages. OO in fig. 32. represents the box of this piston, fitted to the working barrel in any of the preceding ways as may be thought best. AB is a cross bar of four arms, which is fixed to the top of the box. CF is the piston-rod going through a hole in the middle of AB, and reaching a little way beyond the bottom of the box. It has a shoulder D, which prevents it going too far through. On the lower end there is a thick metal plate, turned conical on its upper side, so as to fit a conical seat PP in the bottom of the piston-box.

When the piston-rod is pushed down, the friction on the barrel prevents the box from immediately yielding. The rod therefore slips through the hole of the cross bar AB. The plate E, therefore, detaches itself from the box. When the shoulder D presses on the bar AB, the box must yield, and be pushed down the barrels, and the water gets up through the perforation.

Pump. When the piston-rod is drawn up again, the box does not move till the plate E lodged in the seat PP, and thus shuts the water-way; and then the piston lifts the water which is above it, and acts as the piston of a sucking pump.

This is a very simple and effective construction, and makes a very tight valve. It has been much recommended by engineers of the first reputation, and is frequently used; and from its simplicity, and the great solidity of which it is capable, it seems very fit for great works. But it is evident that the water-way is limited to less than one-half of the area of the working-barrel. For if the perforation of the piston be one-half of the area, the diameter of the plate or ball EF must be greater; and therefore less than half the area will be left for the passage of the water by its sides.

We come now to consider the forms which may be given to the valves of a hydraulic engine.

The requisites of a valve are, that it shall be tight, of sufficient strength to resist the great pressures to which it is exposed, that it afford a sufficient passage for the water, and that it do not allow much to go back while it is shutting.

We have not much to add to what has been said already on this subject. The valves which accompany the pump of fig. 5. are called *clack valves*, and are of all the most obvious and common; and the construction described on that occasion is as perfect as any. We only add, that as the leather is at last destroyed at the hinge by such incessant motion, and it is troublesome, especially in deep mines, and under water, to undo the joint of the pump in order to put in a new valve, it is frequently annexed to a box like that of a piston, made a little conical on the outside, so as to fit a conical seat made for it in the pipe, as represented in fig. 33. and it has an iron handle like that of a basket, by which it can be laid hold of by means of a long grappling-hook let down from above. Thus it is drawn up; and being very gently tapered on the sides, it sticks very fast in its place.

The only defect of this valve is, that by opening very wide when pushed up by the stream of water, it allows a good deal to go back during its shutting again. In some great machines which are worked by a slow turning crank, the return of the piston is so very slow, that a sensible loss is incurred by this; but it is nothing like what Dr Defaguliers says, one-half of a cylinder whose height is equal to the diameter of the valve.—For in such machines, the last part of the upward stroke is equally slow, and the velocity of the water through the valve exceedingly small, so that the valve is at this time almost shut.

The butterfly-valve represented in figures 29, &c. is free from most of those inconveniences, and seems the most perfect of the clack valves. Some engineers make their great valves of a pyramidal form, consisting of four clacks, whose hinges are in the circumference of the water-way, and which meets with their points in the middle, and are supported by four ribs which rise up from the sides, and unite in the middle. This is an excellent form, affording the most spacious water-way, and shutting very readily. It seems to be the best possible for a piston. The rod of the piston is branched out on four sides, and the branches go through the piston-box, and are fastened below with screws. These branches

Utility of the butterfly-valves.

Pump. branches form the support for the four clacks. We have seen a valve of this form in a pump of six feet diameter, which discharged 20 hogheads of water every stroke, and made 12 strokes in a minute, raising the water above 22 feet.

70
Button valves
There is another form of valve, called the *button or tail valve*. It consists of a plate of metal AB (fig. 34.) turned conical, so as exactly to fit the conical cavity *a b* of its box. A tail CD projects from the under side, which passes through a cross-bar EF in the bottom of the box, and has a little knob at the end, to hinder the valve from rising too high.

71
Very useful;
This valve, when nicely made, is unexceptionable. It has great strength, and is therefore proper for all severe strains, and it may be made perfectly tight by grinding. Accordingly it is used in all cases where this is of indispensable consequence. It is most durable, and the only kind that will do for passages where steam or hot water is to go through. Its only imperfection is a small water-way; which, from what has been said, cannot exceed, nor indeed equal, one-half of the area of the pipe.

72
Though somewhat imperfect in the water-way.
If we endeavour to enlarge the water-way, by giving the cone very little taper, the valve frequently sticks so fast in the seat that no force can detach them.— And this sometimes happens during the working of the machine and the jolts and blows given to the machine in taking it to pieces, in order to discover what has been the reason that it has discharged no water, frequently detaches the valve, and we find it quite loose, and cannot tell what has deranged the pump. When this is guarded against, and the diminution of the water-way is not of very great consequence, this is the best form of a valve.

73
A very simple valve described.
Analogous to this is the simplest of all valves, represented in fig. 35. It is nothing more than a sphere of metal A, to which is fitted a seat with a small portion BC of a spherical cavity. Nothing can be more effectual than this valve; it always falls into its proper place, and in every position fits it exactly. Its only imperfection is the great diminution of the water-way. If the diameter of the sphere does not considerably exceed that of the hole, the touching parts have very little taper, and it is very apt to stick fast. It opposes much less resistance to the passage of the water than the flat under-surface of the button-valve. *N. B.* It would be an improvement of that valve to give it a taper-shape below like a boy's top. The spherical valve must not be made too light, otherwise it will be hurried up by the water, and much may go back while it is returning to its place.

74
A valve by Belidor uniting every requisite.
Belidor describes with great minuteness (vol. ii p. 221, &c.) a valve which unites every requisite. But it is of such nice and delicate construction, and its defects are so great when this exactness is not attained, or is impaired by use, that we think it hazardous to introduce it into a machine in a situation where an intelligent and accurate artist is not at hand. For this reason we have omitted the description, which cannot be given in few words, nor without many figures; and desire our curious readers to consult that author, or peruse Dr Desaguliers's translation of this passage. Its principle is precisely the same with the following rude contrivance with which we shall conclude the descriptive part of this article.

Pump. Suppose ABCD (fig. 36.) to be a square wooden trunk. EF is a piece of oak-board, exactly fitted to the trunk in an oblique position, and supported by an iron pin which goes through it at I, one-third of its length from its lower extremity E. The two ends of this board are levelled, so as to apply exactly to the sides of the trunk. It is evident, that if a stream of water comes in the direction BA, its pressure on the part IF of this board will be greater than that upon EI. It will therefore force it up and rush through, making it stand almost parallel to the sides of the trunk. To prevent its rising so far, a pin must be put in its way. When this current of water changes its direction, the pressure on the upper side of the board being again greatest on the portion IF, it is forced back again to its former situation; and its two extremities resting on the opposite sides of the trunk, the passage is completely stopped. This board therefore performs the office of a valve; and this valve is the most perfect that can be, because it offers the freest passage to the water, and it allows very little to get back while it is shutting; for the part IE brings up half as much water as IF allows to go down. It may be made extremely tight, by fixing two thin fillets H and G to the sides of the trunk, and covering those parts of the board with leather which applies to them; and in this state it perfectly resembles Belidor's fine valve.

75
Another principle.
And this construction of the valve suggests, by the way, a form of an occasional pump, which may be quickly set up by any common carpenter, and will be very effectual in small heights. Let *abcde* (fig. 36.) be a square box made to slide along this wooden trunk without shake, having two of its sides projecting upwards, terminating like the gable-ends of a house. A piece of wood *e* is mortised into these two sides, and to this the piston-rod is fixed. This box being furnished with a valve similar to the one below, will perform the office of a piston. If this pump be immersed so deep in the water that the piston shall also be under water, we scruple not to say that its performance will be equal to any. The piston may be made abundantly tight by covering its outside neatly with soft leather. And as no pipe can be bored with greater accuracy than a very ordinary workman can make a square trunk, we presume that this pump will not be very deficient even for a considerable suction.

77
The motion of water in pumps.
We now proceed to the last part of the subject, to consider the motion of water in pumps, in reference to the force which must be employed. What we have hitherto said with respect to the force which must be applied to a piston, related only to the sustaining the water at a certain height: but in actual service we must not only do this, but we must discharge it at the place of delivery in a certain quantity; and this must require a force superadded, to what is necessary for its mere support at this height.

78
An intricate subject.
This is an extremely intricate and difficult subject, and very imperfectly understood even by professed engineers. The principles on which this knowledge must be founded are of a much more abstruse nature than the ordinary laws of hydrostatics; and all the genius of Newton was employed in laying the foundation of this part of physical science. It has been much cultivated in the course of this century by the first mathematicians of Europe. Daniel and John Bernoulli have written very

Pump.
79
The theory
denomina-
ted Hydro-
dynamics,

very elaborate treatises on the subject, under the very opposite name of HYDRODYNAMICS; in which, although they have added little or nothing to the fundamental propositions established in some sort by Newton, and acquiesced in by them, yet they have greatly contributed to our progress in it by the *methods* which they have pursued in making application of those fundamental propositions to the most important cases. It must be acknowledged, however, that both these propositions, and the extensions given them by these authors, are supported by a train of argument that is by no means unexceptionable; and that they proceed on assumptions or postulates which are but nearly true in any case, and in many are inadmissible: and it remains to this hour a wonder or puzzle how these propositions and their results correspond with the phenomena which we observe.

But fortunately this correspondence does obtain to a certain extent. And it seems to be this correspondence chiefly which has given these authors, with Newton at their head, the confidence which they place in their respective principles and methods: for there are considerable differences among them in those respects; and each seems convinced that the others are in a mistake. Messieurs d'Alembert and De la Grange have greatly corrected the theories of their predecessors, and have proceeded on postulates which come much nearer to the real state of the case. But their investigations involve us in such an inextricable maze of analytical investigation, that even when we are again conducted to the light of day by the clue which they have given us, we can make no use of what we there discovered.

80
Though
imperfect
is very
useful.

But this theory imperfect as it is, is of great service. It generalizes our observations and experiments, and enables us to compose a *practical doctrine* from a heap of facts which otherwise must have remained solitary and unconnected, and as cumbersome in their application as the characters of the Chinese writing.

81
Fundamen-
tal proposi-
tion.

The fundamental proposition of this practical hydrodynamics is, that water or any fluid contained in an open vessel of indefinite magnitude, and impelled by its weight only, will flow through a small orifice with the velocity which a heavy body would acquire by falling from the horizontal surface of the fluid. Thus, if the orifice is 16 feet under the surface of the water, it will issue with the velocity of 32 feet in a second.

Its velocity corresponding to any other depth h of the orifice under the surface, will be had by this easy proportion: "As the square root of 16 is to the square root of h ; so is 32 feet to the velocity required: or,

alternately, $\sqrt{16} : 32 = \sqrt{h} : v$, and $v = \frac{32\sqrt{h}}{\sqrt{16}} =$

$\frac{32}{4}\sqrt{h} = 8\sqrt{h}$: that is multiply the square root of the height in feet by eight, and the product is the required velocity.

On the other hand, it frequently occurs, that we want to discover the depth under the surface which will produce a known velocity v . Therefore $\sqrt{h} = \frac{v}{8}$,

and $h = \frac{v^2}{64}$: that is, divide the square of the velocity by 64, and the quotient is the depth wanted in feet.

This proposition is sufficient for all our purposes. For since water is nearly a perfect fluid, and propagates all impressions undiminished, we can, in place of any pressure of a piston or other cause, substitute a perpendicular column of water whose weight is equal to this pressure, and will therefore produce the same efflux.— Thus, if the surface of a piston is half a square foot, and it be pressed down with the weight of 500 pounds, and we would wish to know with what velocity it would cause the water to flow through a small hole, we know that a column of water of this weight, and of half a foot base, would be 16 feet high. And this proposition teaches us, that a vessel of this depth will have a velocity of efflux equal to 32 feet in a second.

If therefore our pressing power be of such a kind that it can continue to press forward the piston with the force of 500 pounds, the water will flow with this velocity, whatever be the size of the hole. All that remains is, to determine what change of *actual pressure* on the piston results from the motion of the piston itself, and to change the velocity of efflux in the subduplicate ratio of the change of actual pressure.

But before we can apply this knowledge to the circumstances which take place in the motion of water in pumps, we must take notice of an important modification of the fundamental proposition, which is but very obscurely pointed out by any good theory, but is established on the most regular and unexceptionable observation.

If the efflux is made through a hole in a thin plate, and the velocity is computed as above, we shall discover the quantity of water which issues in a second by observing, that it is a prism or cylinder of the length indicated by the velocity, and having its transverse section equal to that of the orifice. Thus, in the example already given, supposing the hole to be a square inch, the solid contents of this prism, or the quantity of water issuing in a second, is $1 \times 32 \times 12$ cubic inches, or 384 cubic inches. This we can easily measure by receiving it in a vessel of known dimensions. Taking this method, we uniformly find a deficiency of nearly 38 parts in 100; that is, if we should obtain 100 gallons in any number of seconds, we shall in fact get only 62. This is a most regular fact, whether the velocities are great or small, and whatever be the size and form of the orifice. The deficiency increases indeed in a very minute degree with the velocities. If, for instance, the depth of the orifice be one foot, the discharge is $\frac{62.13}{100}$; if it be 15 feet, the discharge is $\frac{61.79}{100}$.

This deficiency is not owing to a diminution of velocity; for the velocity may be easily and accurately measured by the distance to which the jet will go, if directed horizontally. This is found to correspond very nearly with the proposition, making a very small allowance for friction at the border of the hole, and for the resistance of the air. Sir Isaac Newton ascribed the deficiency with great justice to this, that the lateral columns of water, surrounding the column which is incumbent on the orifice, press towards the orifice, and contribute to the expence equally with that column. These lateral filaments, therefore, issue obliquely, crossing the motion of the central stream, and produce a contraction of the jet; and the whole stream does not acquire a parallel motion and its ultimate velocity till it

Pump.
82
its utility.

83
Remark
previous
to its ap-
plication.

Pump. has got to some distance from the orifice. Careful observation showed him that this was really the case. But even his genius could not enable him to ascertain the motion of the lateral filaments by theory, and he was obliged to measure every thing as he saw it. He found the diameter of the jet at the place of the greatest contraction to be precisely such as accounted for the deficiency. His explication has been unanimously acquiesced in; and experiments have been multiplied to ascertain all those circumstances which our theory cannot determine *a priori*. The most complete set of experiments are those of Michelotti, made at Turin at the expense of the prince of Piedmont. Here jets were made of 1, 2, 3, and 4 inches diameter; and the water received into cisterns most accurately formed of brick, and lined with stucco. It is the result of these experiments which we have taken for a measure of the deficiency.

We may therefore consider the water as flowing through a hole of this contracted dimension, or substitute this for the real orifice in all calculations. For it is evident that if a mouth-piece (so to call it) were made, whose internal shape precisely tallied with the form which the jet assumes, and if this mouth-piece be applied to the orifice, the water will flow out without any obstruction. The vessel may therefore be considered as really having this mouth-piece.

Nay, from this we derive a very important observation, "that if, instead of allowing the water to flow through a hole of an inch area made in a thin plate, we make it flow through a hole in a thick plank, so formed that the external orifice shall have an inch area, but be widened internally agreeably to the shape which nature forms, both the velocity and quantity will be that which the fundamental proposition determines. Michelotti measured with great care the form of the great jets of three and four inches diameter, and found that the bounding curve was an elongated trochoid. He then made a mouth-piece of this form for his jet of one inch, and another for his jet of two inches; and he found the discharges to be $\frac{9}{10}\frac{7}{8}$ and $\frac{9}{10}\frac{7}{8}$; and he, with justice, ascribed the trifling deficiency which still remained, partly to friction and partly to his not having exactly suited his mouth-piece to the natural form. We imagine that this last circumstance was the sole cause: For, in the first place, the water in his experiments, before getting at his jet-holes, had to pass along a tube of eight inches diameter. Now a jet of four inches bears too great a proportion to this pipe; and its narrowness undoubtedly hindered the lateral columns from contributing to the efflux in their due proportion, and therefore rendered the jet less convergent. And, in the next place, there can be no doubt (and the observations of Daniel Bernoulli confirm it) but that this convergency begins within the vessel, and perhaps at a very considerable distance from the orifice. And we imagine, that if accurate observations could be made on the motion of the remote lateral particles within the vessel, and an internal mouth-piece were shaped according to the curve which is described by the remotest particle that we can observe, the efflux of water would almost perfectly tally with the theory. But indeed the coincidence is already sufficiently near for giving us very valuable information. We learn that the quantity of water which flows through a hole, in consequence of its own weight, or by the action of any force, may be

Vol. XV.

increased one half by properly shaping the passage to this hole; for we see that it may be increased from 62 to nearly 99.

But there is another modification of the efflux, which we confess our total incapacity to explain. If the water issues through a hole made in a plate whose thickness is about twice the diameter of the hole, or, to express it better, if it issues through a pipe whose length is about twice its diameter, the quantity discharged is nearly $\frac{9}{10}\frac{7}{8}$ of what results from the proposition. If the pipe be longer than this, the quantity is diminished by friction, which increases as the length of the pipe increases. If the pipe be shorter, the water will not fill it, but detaches itself at the very entry of the pipe, and flows with a contracted jet. When the pipe is of this length, and the extremity is stopped with the finger, so that it begins to flow with a full mouth, no subsequent contraction is observed; but merely striking on the pipe with a key or the knuckle is generally sufficient to detach the water in an instant from the sides of the pipe, and reduce the efflux to $\frac{9}{10}\frac{7}{8}$.

This effect is most unaccountable. It certainly arises from the mutual adhesion or attraction between the water and the sides of the pipe; but how this, acting at right angles to the motion, should produce an increase from 62 to 82, nearly $\frac{1}{3}$, we cannot explain. It shows, however, the prodigious force of this attraction, which in the space of two or three inches is able to communicate a great velocity to a very great body of water. Indeed the experiments on capillary tubes show that the mutual attraction of the parts of water is some thousands of times greater than their weight.

We have only further to add, that every increase of pipe beyond two diameters is accompanied with a diminution of the discharge; but in what ratio this is diminished it is very difficult to determine. We shall only observe at present that the diminution is very great. A pipe of 2 inches diameter and 30 feet long has its discharge only $\frac{4}{5}$ of what it would be if only 4 inches long. If its length be 60 feet, its discharge will be no more than $\frac{3}{4}$. A pipe of 1 inch diameter would have a discharge of $\frac{4}{5}$, and $\frac{3}{4}$, in the same situation. Hence we may conclude that the discharge of a 4-inch pipe of 30 feet long will not exceed $\frac{1}{3}$ of what it would be if only 8 inches long. This will suffice for our present purposes; and the determination of the velocities and discharges in long conduits from pump-machines must be referred to the article *WATER-Works*. At present we shall confine our attention to the pump itself, and to what will contribute to its improvement.

Before we can proceed to apply this fundamental proposition to our purpose, we must anticipate in a loose way a proposition of continual use in the construction of *WATER-Works*.

Let water be supposed stagnant in a vessel EFGH (fig. 37.), and let it be allowed to flow out by a cylindrical pipe HIKL, divided by any number of partitions B, C, D, &c. Whatever be the areas B, C, D of these orifices, the velocity in the intermediate parts of the pipe will be the same; for as much passes through any one orifice in a second as passes through any other in the same time, or through any section of the intervening pipe. Let this velocity in the pipe be V, and let the area of the pipe be A. The velocity in the ori-

4 P

fices

Pump.

Pump. fices B, C, D, must be $\frac{VA}{B}$, $\frac{VA}{C}$, $\frac{VA}{D}$, &c. Let g be the velocity acquired in a second by a heavy body. Then, by the general proposition, the height of water in the vessel which will produce the velocity $\frac{VA}{B}$ in the first orifice alone, is $\frac{V^2 A^2}{2gB^2}$. After this passage the velocity is again reduced to V in the middle of the space between the first and second orifices. In the second orifice this velocity is changed to $\frac{VA}{C}$. This alone would have required a height of water $\frac{V^2 A^2}{2gC^2}$. But the water is already moving with the velocity V , which would have resulted from a height of water in vessel (which we shall, in the language of the art, call the HEAD OF WATER) equal to $\frac{V^2}{2g}$. Therefore there is only required a head of water $\frac{V^2 A^2}{2gC^2} - \frac{V^2}{2g}$, or $\frac{V^2}{2g} \times \frac{A^2}{C^2} - 1$. Therefore the whole height necessary for producing the efflux through both orifices, so as still to preserve the velocity V in the intervening pipe, is $\frac{V^2}{2g} \times \frac{A^2}{B^2} + \frac{A^2}{C^2} - 1$. In like manner the third orifice D would alone require a head of water $\frac{V^2}{2g} \times \frac{A^2}{D^2} - 1$; and all the three would require a head $\frac{V^2}{2g} \times \frac{A^2}{B^2} + \frac{A^2}{C^2} + \frac{A^2}{D^2} - 2$. By this induction may easily be seen what head is necessary for producing the efflux through any number of orifices.

Let the expence or quantity of water discharged in an unit of time (suppose a second) be expressed by the symbol Q . This is measured by the product of the velocity by the area of the orifice, and is therefore $= VA$, or $\frac{VA}{B} \times B$, or $\frac{VA}{C} \times C$, &c. and $V^2 = \frac{Q^2}{A^2}$. Therefore we may compute the head of water (which we shall express by H) in reference to the quantity of water discharged, because this is generally the interesting circumstance. In this view we have $H = \frac{Q^2}{2gA^2} \times \frac{A^2}{B^2} + \frac{A^2}{C^2} + \frac{A^2}{D^2} - 2$: which shows that the head of water necessary for producing the discharge increases in the proportion of the square of the quantity of water which is discharged.

84
To determine the motion of water, &c.

These things being premised, it is an easy matter to determine the motion of water in a pump, and the quantity discharged, resulting from the action of any force on the piston, or the force which must be applied to the piston in order to produce any required motion or quantity discharged. We have only to suppose that the force employed is the pressure of a column of water of the diameter of the working barrel; and this is over

and above the force which is necessary for merely supporting the water at the height of the place of delivery. The motion of the water will be the same in both cases.

Let us, first of all, consider a sucking-pump. The motion here depends on the pressure of the air, and will be the same as if the pump were lying horizontally, and communicated with a reservoir, in which is a head of water sufficient to overcome all the obstructions to the motion, and produce a velocity of efflux such as we desire. And here it must be noted that there is a limit. No velocity of the piston can make the water rise in the suction-pipe with a greater velocity than what would be produced by the pressure of a column of water 33 feet high; that is, about 46 feet *per* second.

Let the velocity of the piston be V , and the area of the working barrel be A . Then, if the water fills the barrel as fast as the piston is drawn up, the discharge during the rise of the piston, or the number of cubic feet of water *per* second, must be $= V \times A$. This is always supposed, and we have already ascertained the circumstances which ensure this to happen. If, therefore, the water arrived with perfect freedom to the piston, the force necessary for giving it this velocity, or for discharging the quantity $V \times A$ in a second, would be equal to the weight of the pillar of water whose height is $\frac{V^2}{2g}$, and base A .

It does not appear at first sight that the force necessary for producing this discharge has any thing to do with the obstructions to the ascent of the water into the pump, because this is produced by the pressure of the atmosphere, and it is the action of this pressure which is measured by the head of water necessary for producing the internal motion in the pump. But we must always recollect that the piston, before bringing up any water, and supporting it at a certain height, was pressed on both sides by the atmosphere. While the air supports the column below the piston, all the pressure expended in this support is abstracted from its pressure on the under part of the piston, while its upper part still supports the whole pressure. The atmosphere continues to press on the under surface of the piston, through the intermedium of the water in the suction-pipe, with the difference of these two forces.—Now, while the piston is drawn up with the velocity V , more of the atmospheric pressure must be expended in causing the water to follow the piston; and it is only with the remainder of its whole pressure that it continues to press on the under surface of the piston. Therefore, in order that the piston may be raised with the velocity V , a force must be applied to it, over and above the force necessary for merely supporting the column of water, equal to that part of the atmospheric pressure thus employed; that is, equal to the weight of the head of water necessary for forcing the water up through the suction-pipe, and producing the velocity V in the working barrel.

Therefore Let B be the area of the mouth of the suction-pipe, and C the area of the fixed valve, and let the suction-pipe be of equal diameter with the working barrel. The head necessary for producing the velocity V on the working barrel is $\frac{V^2}{2g} \left(\frac{A^2}{B^2} + \frac{A^2}{C^2} - 1 \right)$. If d express the density of water; that is, if d be the number

Pump.

In the sucking-pump,

Pump. number of pounds in a cubic foot of water, then $dA \frac{V^2}{2g} \frac{A^2 V^2}{b^2}$. After this the velocity is changed to $\frac{AV}{a}$ in *Pump.* will express the weight of a column whose base is A , and height $\frac{V^2}{2g}$, all being reckoned in feet. Therefore the force which must be applied, when estimated in pounds, will be $p = \frac{dAV^2}{2g} \left(\frac{A^2}{B^2} + \frac{A^2}{C^2} - 1 \right)$

The first general observation to be made on what has been said is, that the power which must be employed to produce the necessary motion, in opposition to all the obstacles, is in the proportion of the square of the velocity which we would produce, or the square of the quantity of water we would discharge.

We have hitherto proceeded on the supposition, that there is no contraction of the jet in passing through these two orifices. This we know would be very far from the truth. We must therefore accommodate things to these circumstances, by diminishing B and C in the ratio of the contraction, and calling the diminished areas b and c ; then we have $p = \frac{dAV^2}{2g} \left(\frac{A^2}{b^2} + \frac{A^2}{c^2} - 1 \right)$.

What this diminution may be, depends on the form of the parts. If the fixed valve, and the entry into the pump, are simply holes in thin plates, then $b = \frac{6}{8} B$ and $c = \frac{6}{8} C$. The entry is commonly widened or trumpet-shaped, which diminishes greatly the contraction: but there are other obstacles in the way arising from the strainer usually put round it to keep out filth. The valve may have its contraction already diminished also by its box being made bell-shaped internally; nay, even giving it a cylindrical box, in the manner of fig. 33. is better than no box at all, as in fig. 5.; for such a cylindrical box will have the unaccountable effect of the short tube, and make $b = \frac{6}{8} B$, instead of $\frac{6}{8} B$. Thus we see that circumstances seemingly very trifling may produce great effects in the performance of a pump. We should have observed that the valve itself presents an obstacle which diminishes the motion and requires an increase of power; and it would seem that in this respect the clack or butterfly valve is preferable to the button valve.

Example. Suppose the velocity of the piston to be 2 feet or 24 inches *per* second, and that the two contracted areas are each $\frac{1}{2}$ of the area of the pump, which is not much less than what obtains in ordinary pumps. We have $\frac{V^2}{2g} \left(\frac{A^2}{b^2} + \frac{A^2}{c^2} - 1 \right) = \frac{526}{8} (25 + 25 - 1) = 36.75$ inches, and the force which we must add to what will merely support the column is the weight of a pillar of water incumbent on the piston, and something more than three feet high. This would be a sensible portion of the whole force in raising water to small heights.

We have supposed the suction-pipe to be of the same diameter with the working barrel; but it is usual to make it of smaller diameter, generally equal to the water way of the fixed valve. This makes a considerable change in the force necessary to be applied to the piston. Let a be the area of the suction-pipe, the area of the entry being still B ; and the equivalent entry without contraction being still b , we have the velocity at the entrance $= \frac{AV}{b}$, and the producing head of water =

this change a head of water equal to $\frac{A^2 V^2}{2g a^2}$. But the velocity retained in the suction-pipe is equivalent to the effect of a head of water $\frac{A^2 V^2}{2g a^2}$. Therefore the head necessary for producing such a current through the fixed valve, that the water may follow the piston with the velocity V , is $\frac{A^2 V^2}{2g b^2} + \frac{A^2 V^2}{2g c^2} - \frac{A^2 V^2}{2g a^2}$, or = $\frac{V^2}{2g} \left(\frac{A^2}{b^2} + \frac{A^2}{c^2} - \frac{A^2}{a^2} \right)$. This is evidently less than before, because a is less than A , and therefore $\frac{A^2}{a^2}$

is greater than unity, which was the last term of the former formula. There is some advantage therefore, derived from making the diameter of the suction-pipe less than that of the working barrel: but this is only because the passage of the fixed valve is smaller, and the inspection of the formula plainly points out that the area of the suction-pipe should be equal to that of the fixed valve. When it is larger, the water must be accelerated in its passage through the valve; which is an useless expence of force, because this velocity is to be immediately reduced to V in the working-barrel. If the foregoing example be computed with a equal to $\frac{1}{4}$ of A , we shall find the head H equal to 29 inches instead of 37.

But this advantage of a smaller suction-pipe is in all cases very moderate; and the pump is always inferior to one of uniform dimensions throughout, having the orifice at the fixed valve of the same area. And if these orifices are considerably diminished in any proportion, the head necessary for overcoming the obstacles, so that the required velocity V may still be produced in the working barrel, is greatly increased. If we suppose the area $a \frac{1}{2}$ of A , which is frequently done in house pumps, where the diameter of the suction-pipe does seldom exceed $\frac{1}{2}$ of that of the working-barrel; and suppose every thing made in proportion to this, which is also usual, because the unskilled pump-makers study a symmetry which satisfies the eye; we shall find that the pump taken as an example will require a head of water = 13 feet and upwards. Besides, it must be observed that the friction of the suction-pipe itself has not been taken into the account. This alone is greater, in most cases, than all the obstructions we have been speaking of; for if this pipe is three inches diameter, and that of the working-barrel is six, which is reckoned a liberal allowance for a suction-pipe, and if the fixed valve is 25 feet above the surface of the pit-water; the friction of this pipe will amount to one-third of the whole propelling force,

Thus we have enabled the reader to ascertain the force necessary for producing any required discharge of water from a pump of known dimensions: and the converse of this determination gives us the discharge which will be produced by any given force. For making $\frac{A^2}{b^2} + \frac{A^2}{c^2} - \frac{A^2}{a^2}$, (which is a known quantity, resulting from the dimensions of the pump) = M , we

Pump. have $H = \frac{V^2}{2g} M$, and $V^2 = \frac{2gH}{M}$, and $V =$

$$\sqrt{\frac{2gH}{M}}. \text{ Now } H \text{ is that part of the natural power}$$

which we have at command which exceeds what is necessary for merely supporting the column of water. Thus, if we have a pump whose piston has an area of $\frac{1}{4}$ of a square foot, its diameter being $6\frac{1}{4}$ inches; and we have to raise the water 32 feet, and can apply a power of 525 pounds to the piston; we wish to know at what rate the piston will be moved, and the quantity of water discharged? Merely to support the column of water of this height and diameter, requires 500 pounds. Therefore the remaining power, which is to produce the motion, is 25 pounds. This is the weight of a column 1 foot 4 inches high, and $H = 1,333$ feet. Let us suppose the diameter of the suction-pipe $\frac{1}{2}$ of that of the working-barrel, so that $\frac{A}{B} = 4$. We may suppose

it executed in the best manner, having its lower extremity trumpet-shaped, formed by the revolution of the proper trochoid. The contraction at the entry may therefore be considered as nothing, and $\frac{A}{b} = 4$, and $\frac{A^2}{b^2} = 16$. We may also suppose the orifice of the fixed valve equal to the area of the suction-pipe, so that $\frac{A^2}{C^2}$ is also $= 16$, and there is no contraction here; and therefore $\frac{A^2}{c^2}$ is also 16. And lastly, $\frac{A^2}{a^2}$ is also 16.

Therefore $\frac{A^2}{b^2} + \frac{A^2}{c^2} - \frac{A^2}{a^2}$ or $M = 16 + 16 - 16$, $= 16$. We have also $2g = 64$. Now $V = \sqrt{\frac{2gH}{M}}$

$$= \sqrt{\frac{64 \times 1,333}{16}}, = 2,309 \text{ feet, and the piston will}$$

move with the velocity of 2 feet 4 inches nearly. Its velocity will be less than this, on account both of the friction of the piston and the friction of the water in the suction-pipe. These two circumstances will probably reduce it to one foot eight inches; and it can hardly be less than this.

We have taken no notice of the friction of the water in the working-barrel, or in the space above the piston; because it is in all cases quite insignificant. The longest pipes employed in our deep mines do not require more than a few inches of head to overcome it.

But there is another circumstance which must not be omitted. This is the resistance given to the piston in its descent. The pistons of an engine for drawing water from deep mines must descend again by their own weight in order to repeat their stroke. This must require a preponderance on that end of the working-beam to which they are attached, and this must be overcome by the moving power during the effective stroke. It makes, therefore, part of the whole work to be done, and must be added to the weight of the column of water which must be raised.

This is very easily ascertained. Let the velocity of the piston in its descent be V , the area of the pump-barrel A , and the area of the piston-valve a . It is evident, that while the piston descends with the velocity V , the water which is displaced by the piston in a second is $(A-a)V$. This must pass through the hole

of the piston, in order to occupy the space above, which is left by the piston. If there were no contraction, the Pump.

water would go thro' with the velocity $\frac{A-a}{a} V$; but as there will always be some contraction, let the diminished area of the hole (to be discovered by experiment) be b ; the velocity therefore will be $V \frac{A-a}{b}$. This requires for its production a head of water $\frac{V^2}{2g} \left(\frac{A-a}{b} \right)^2$.

This is the height of a column of water whose base is not A but $A-a$. Calling the density of water d , we have for the weight of this column, and the force p is $d \times A-a \times \left(\frac{A-a}{b} \right)^2 \times \frac{V^2}{2g} = \frac{d V^2 (A-a)^3}{2g b^2}$. This we see again, is proportional to the square of the velocity of the piston in its descent, and has no relation to the height to which the water is raised.

If the piston has a button valve, its surface is at least equal to a ; and therefore the pressure is exerted on the water by the whole surface of the piston. In this case

we shall have $p = \frac{d V^2 A^3}{2g b^2}$ considerably greater than

before. We cannot ascertain this value with great precision, because it is extremely difficult, if possible, to determine the resistance in so complicated a case. But the formula is exact, if b can be given exactly; and we know within very moderate limits what it may amount to. In a pump of the very best construction, with a button valve, b cannot exceed one-half of A ;

and therefore $\frac{A^3}{b^2}$ cannot be less than 8. In this case, $\frac{V^2 A^3}{2g b^2}$ will be $\frac{V^2}{8}$. In a good steam-engine pump V is about three feet per second, and $\frac{V^2}{8}$ is about $1\frac{1}{8}$ feet, which is but a small matter.

We have hitherto been considering the sucking-⁸⁶ pump alone: but the forcing pump is of more importance, and apparently more difficult of investigation.—^{And in the forcing-pump.} Here we have to overcome the obstruction in long pipes, with many bends, contractions, and other obstructions. But the consideration of what relates merely to the pump is abundantly simple. In most cases we have only to force the water in an air-vessel, in opposition to the elasticity of the air compressed in it, and to send it thither with a certain velocity, regulated by the quantity of water discharged in a given time. The elasticity of the air in the air-vessel propels it along the *Main*. We are not now speaking of the force necessary for counterbalancing this pressure of the air in the air-vessel, which is equivalent to all the subsequent obstructions, but only of the force necessary for propelling the water out of the pump with the proper velocity.

We have in a manner determined this already. The piston is solid, and the water which it forces has to pass through a valve in the lateral pipe, and then to move in the direction of the *Main*. The change of direction requires an addition of force to what is necessary for merely impelling the water through the valve. Its quantity is not easily determined by any theory, and it varies according to the abruptness of the turn. It appears from experiment, that when a pipe is bent to a right angle, without any curvature or rounding, the velocity is diminished about $\frac{1}{16}$. This would aug-

ment

Pump. ment the head of water about $\frac{1}{8}$. This may be added to the contraction of the valve hole. Let c be its natural area, and whatever is the contraction competent to its form increase it $\frac{1}{8}$, and call the contracted area

c . Then this will require a head of water = $\frac{V^2 A^2}{2 g c^2}$

This must be added to the head $\frac{V^2}{2g}$, necessary for merely giving the velocity V to the water. Therefore the whole is $\frac{V^2}{2g} \left(\frac{A^2}{c^2} + 1 \right)$; and the power p necessary for this purpose is $\frac{d A V^2}{2 g} \left(\frac{A^2}{c^2} + 1 \right)$.

It cannot escape the observation of the reader, that in all these formulæ, expressing the height of the column of water which would produce the velocity V in the working barrel of the pump, the quantity which multiplies the constant factor $\frac{d A V^2}{2 g}$ depends on the

contracted passages which are in different parts of the pump, and increases in the duplicate proportion of the sum of those contractions. It is therefore of the utmost consequence to avoid all such, and to make the Main which leads from the forcing-pump equal to the working barrel. If it be only of half the diameter, it has but one-fourth of the area, the velocity in the Main is four times greater than that of the piston, and the force necessary for discharging the same quantity of water is 16 times greater.

It is not, however, possible to avoid these contractions altogether, without making the main pipe wider than the barrel. For if only so wide, with an entry of the same size, the valve makes a considerable obstruction. Unskilful engineers endeavour to obviate this by making an enlargement in that part of the Main which contains the valve. This is seen in fig. 14. at the valve L. If this be not done with great judgment, it will increase the obstructions. For if this enlargement is full of water, the water must move in the direction of its axis with a diminished velocity; and when it comes into the main, it must again be accelerated. In short, any abrupt enlargement which is to be afterwards contracted, does as much harm as a contraction, unless it be so short that the water in the axis keeps its velocity till it reaches the contraction. Nothing would do more service to an artist, who is not well founded in the theory of hydrodynamics, than to make a few simple and cheap experiments with a vessel like that of fig. 37. Let the horizontal pipe be about three inches diameter, and made in joints which can be added to each other. Let the joints be about six inches long, and the holes from one-fourth to a whole inch in diameter. Fill the vessel with water, and observe the time of its sinking three or four inches. Each joint should have a small hole in its upper side to let out the air; and when the water runs out by it, let it be stopped by a peg. He will see that the larger the pipe is in proportion to the orifices made in the partitions, the efflux is more diminished. We believe that no person would suspect this who has not considered the subject minutely.

All angular enlargements, all boxes, into which the pipes from different working barrels, unite their water before it goes into a Main, must therefore be avoided by an artist who would execute a good machine; and the different contractions which are unavoidable at

the seats of valves and the perforations of pistons, &c. should be diminished by giving the parts a trumpet-shape.

In the air-vessels represented in fig. 13. this is of very great consequence. The throat O, through which the water is forced by the expansion of the confined air, should always be formed in this manner. For it is this which produces the motion during the returning part of the stroke in the pump constructed like fig. 13. n° 1. and during the whole stroke in n° 2. Neglecting this seemingly trifling circumstance will diminish the performance at least one-fifth. The construction of n° 1. is the best, for it is hardly possible to make the passage of the other so free from the effects of contraction. The motion of the water during the returning stroke is very much contorted.

There is one circumstance that we have not taken any notice of, viz. the gradual acceleration of the motion of water in pumps. When a force is applied to the piston, it does not in an instant communicate all the velocity which it acquires. It acts as gravity acts on heavy bodies; and if the resistances remained the same, it would produce, like gravity, an uniformly accelerated motion. But we have seen that the resistances (which are always measured by the force which just overcomes them) increase as the square of the velocity increases. They therefore quickly balance the action of the moving power, and the motion becomes uniform, in a time so short that we commit no error of any consequence by supposing it uniform from the beginning. It would have prodigiously embarrassed our investigations to have introduced this circumstance; and it is a matter of mere speculative curiosity: for most of our moving powers are unequal in their exertions, and these exertions are regulated by other laws. The pressure on a piston moved by a crank is as variable as its velocity, and in most cases is nearly in the inverse proportion of its velocity, as any mechanic will readily discover. The only case in which we could consider this matter with any degree of comprehensibility is that of a steam-engine, or of a piston which forces by means of a weight lying on it. In both, the velocity becomes uniform in a very small fraction of a second.

We have been very minute on this subject. For although it is the only view of a pump which is of any importance, it is hardly ever understood even by professed engineers. And this is not peculiar to hydraulics, but is seen in all the branches of practical mechanics. The elementary knowledge to be met with in such books as are generally perused by them, goes no farther than to state the forces which are in equilibrio by the intervention of a machine, or the proportion of the parts of a machine which will set two known forces in equilibrio. But when this equilibrium is destroyed by the superiority of one of the forces, the machine must move; and the only interesting question is, *what will be the motion?* Till this is answered with some precision, we have learned nothing of any importance. Few engineers are able to answer this question even in the simplest cases; and they cannot, from any confident science, say what will be the performance of an untried machine. They guess at it with a success proportioned to the multiplicity of their experience and their own sagacity. Yet this part of mechanics is as susceptible of accurate computation as the cases of equilibrium.—We therefore thought it our duty to point out the manner of proceeding so circumstantially, that every

Puncheon.

step should be plain and easy, and that conviction should always accompany our progress. This we think it has been in our power to do, by the very simple method of substituting a column of water acting by its weight in lieu of any natural power which we may chance to employ.

To such as wish to prosecute the study of this important part of hydraulics in its most abstruse parts, we recommend the perusal of the dissertations of Mr Pitot and Mr Bossut, in the Memoirs of the Academy of Paris; also the dissertations of the Chevalier De la Borda, 1766 and 1767; also the *Hydraulique* of the Chevalier De Buat. We shall have occasion to consider the motion of the water in the mains of forcing or lifting pumps which send the water to a distance, in the article *WATER-Works*; where the reader will see how small is the performance of all hydraulic machines, in comparison of what the usual theories, founded on equilibrium only, would make him expect.

PUN, or PUNN, an expression where a word has at once different meanings. The practice of punning is the miserable refuge of those who wish to pass for wits, without having a grain of wit in their composition.—James the I. of England delighted in punning; and the taste of the sovereign was studied by the courtiers, and even by the clergy. Hence the sermons of that age abound with this species of false wit. It continued to be more or less fashionable till the reign of Queen Anne, when Addison, Swift, Pope, and Arbuthnot, with the other real wits of that classical age, united their efforts to banish punning from polite composition. It is still admitted sparingly in conversation; and no one will deny that a happy pun, when it comes unsought, contributes to excite mirth in a company. A professed *punster*, however, who is always pouring forth his senseless quibbles, as Sancho Panca poured forth his proverbs, is such an intolerable nuisance in society, that we do not wonder at Pope or Swift having written a pamphlet with the title of *God's Revenge against Punning*.

PUNCH, an instrument of iron or steel, used in several arts, for the piercing or stamping holes in plates of metals, &c. being so contrived as not only to perforate, but to cut out and take away the piece. The punch is a principal instrument of the metal-button makers, shoe-makers, &c.

PUNCH is also a name for a sort of compound drink, much used here, and in many parts abroad, particularly in Jamaica, and several other parts of the West-Indies.

Its basis is spring water; which being rendered cooler, brisker, and more acid, with lemon or lime juice, and sweetened again to the palate with fine sugar, makes what they call *sherbet*; to which a proper quantity of spirituous liquor, as brandy, rum, or arrack, being added, the liquor becomes punch.

PUNCHEON, PUNCHIN, or *Punchion*, a little block or piece of steel, on one end whereof is some figure, letter, or mark, engraven either in creux or relievo, impressions whereof are taken on metal, or some other matter, by striking it with a hammer on the end not engraven. There are various kinds of these puncheons used in the mechanical arts; such, for instance, are those of the goldsmiths, cutlers, pewterers, &c.

The puncheon, in coining, is a piece of iron steeled,

whereon the engraver has cut in relievo, the several figures, arms, effigy, inscription, &c. that there are to be in the matrices, wherewith the species are to be marked. Minters distinguish three kinds of puncheons, according to the three kinds of matrices to be made; that of the effigy, that of the cross or arms, and that of the legend or inscription. The first includes the whole portrait in relievo; the second are small, such only containing a piece of the cross or arms; for instance, a fleur-de-lis, an harp, a coronet, &c. by the assemblage of all which the entire matrix is formed. The puncheons of the legend only contain each one letter, and serve equally for the legend on the effigy side and the cross side. See the article COINAGE.

For the puncheons used in stamping the matrices wherein the types of printing characters are cast, see *Letter-FOUNDERT*.

PUNCHEON is also used for several iron tools, of various sizes and figures, used by the engravers en creux on metals. Seal-gravers particularly use a great number for the several pieces of arms, &c. to be engraven, and many stamp the whole seal from a single puncheon.

PUNCHEON, is also a common name for all those iron instruments used by stone-cutters, sculptors, blacksmiths, &c. for the cutting, incising, or piercing their several matters.

Those of sculptors and statuaries serve for the repairing of statues when taken out of the moulds. The locksmiths use the greatest variety of puncheons; some for piercing hot, others for piercing cold; some flat, some square, some round, others oval, each to pierce holes of its respective figure in the several parts of locks.

PUNCHEON, in carpentry, is a piece of timber placed upright between two posts, whose bearing is too great; serving, together with them, to sustain some large weights.

This term is also used for a piece of timber raised upright, under the ridge of a building, wherein the legs of a couple, &c. are jointed.

PUNCHEON, is also the name of a measure for liquids. Rum is brought from the West Indies in puncheons, which are large casks containing about 130 gallons.

PUNCTUATION, in grammar, the art of pointing, or of dividing a discourse into periods, by points expressing the pauses to be made therein.

The points used are four, viz. the period, colon, semi-colon, and comma. See the particular use of each under its proper article, COMMA, COLON, PERIOD, and SEMI-COLON.

In the general, we shall only here observe, that the comma is to distinguish nouns from nouns, verbs from verbs, and such other parts of a period as are not necessarily joined together.—The semi-colon serves to suspend and sustain the period when too long:—the colon, to add some new, supernumerary reason, or consequence, to what is already said:—and the period, to close the sense and construction, and release the voice.

Punctuation is a modern art. The ancients were entirely unacquainted with the use of our commas, colons, &c. and wrote not only without any distinction of members and periods, but also without distinction of words

Puncheon
Punctuation.

Punctua-
tion.

words: which custom, Lipsius observes, continued till the hundred and fourth Olympiad; during which time the sense alone divided the discourse.

What within our own knowledge at this day puts this beyond dispute, is the Alexandrian manuscript, which is at present in the king's library at the British Museum. Whoever examines this, will find, that the whole is written *continuo duēu*, without distinction of words or sentences. How the ancients read their works written in this manner, it is not easy to conceive.

After the practice of joining words together ceased, notes of distinction were placed at the end of every word. In all the editions of the *Fasti Capitolini* these points occur. The same are to be seen on the *Columna Rostrata*. For want of these, we find much confusion in the *Chronicon Almarcum*, and the covenant between the Smyrnæans and Magnesiensians, which are both now at Oxford. In Salmatius's edition of *Dedicatio statuae regillæ Herodis*, the like confusion occurs, where we find ΔΕΤΡΙΤΕ and ΔΕΥΡ ΙΤΕ.

Of these marks of distinction, the Walcote inscription found near Bath may serve for a specimen:

IVLIUS VITALIS FABRI
CESIS LEG XXV VV V
STIPENDIORUM &c.

After every word here, except at the end of a line, we see this mark v. There is an inscription in Mount-faucon, which has a capital letter laid in an horizontal position, by way of interstitial mark, which makes one apt to think that this way of pointing was sometimes according to the fancy of the engraver.

P. FERRARIUS HERMES
CAECINIAE → DIGNAE
CONIVGI → KARRISSIMAE
NVMERIAE → &c.

Here we observe after the words, a T laid horizontally but not after each word, which proves this to be of a much later age than the former.

Having now considered that the present usage of stops was unknown to the ancients, we proceed to assign the time in which this useful improvement of language began.

As it appears not to have taken place while manuscripts and monumental inscriptions were the only known methods to convey knowledge, we must conclude that it was introduced with the art of printing. The 14th century, to which we are indebted for this invention, did not however, bestow those appendages we call *stops*: whoever will be at the pains to examine the first printed books, will discover no stops of any kind; but arbitrary marks here and there, according to the humour of the printer. In the 15th century, we observe their first appearance. We find, from the books of this age, that they were not all produced at the same time; those we meet with there in use, being only the comma, the parenthesis, the interrogation, and the full point. To prove this, we need but look into Bale's Acts of English Notaries, black-letter, printed 1550. Indeed, in the dedication of this book, which is to Edward VI. we discover a colon: but, as this is the only one of the kind throughout the work, it is plain this stop was not established at this time, and so warily put in by the printer; or if it was, that it was not in common use. Thirty years after this time, in that sensible and judicious performance of Sir Thomas Elyot, entitled *The Governour*, imprinted

1580, we see the colon as frequently introduced as any other stop; but the semi-colon and the admiration were still wanting, neither of these being visible in this book. In Hackluyt's voyages, printed 1599, we see the first instance of a semi-colon; and, as if the editors did not fully apprehend the propriety of its general admission, it is but sparingly introduced. The admiration was the last stop that was invented; and seems to have been added to the rest in a period not so far distant from our own time.

Thus we see that these notes of distinction came into use as learning was gradually advanced and improved; one invention indeed, but enlarged by several additions.

PUNCTUM SALIENS, in anatomy, the first rudiments, of the heart in the formation of the foetus where a throbbing motion is perceived. This is said to be easily observed with a microscope in a brood-egg, wherein, after conception, we see a little speck or cloud, in the middle whereof is a spot that appears to beat or leap a considerable time before the foetus is formed for hatching. See the article FOETUS, and ANATOMY, p. 741, &c.

PUNCTUM STANS, a phrase by which the schoolmen vainly attempted to bring within the reach of human comprehension the positive eternity of God. Those subtle reasoners seem to have discovered that nothing, which is made up of parts whether continuous or discrete, can be absolutely infinite, and that therefore eternity cannot consist of a boundless series of successive moments. Yet, as if such a series had always existed and were commensurate in duration with the supreme Being, they compared his eternity to one of the moments which compose the flux of time arrested in its course; and to this eternal moment they gave the name of *punctum stans*, because it was supposed to stand still, whilst the rest followed each other in succession, all vanishing as soon as they appeared. We need not waste time or room in exposing the absurdity of this conceit, as we have elsewhere endeavoured, in the best manner that we can, to ascertain the meaning of the words *eternity* and *infinity*, and to show that they cannot be predicated of time or space, of points or moments, whether flowing or standing still. (See METAPHYSICS, Part II. chap. 7. 8. and Part III. chap. 6.)

PUNCTURE, in surgery, any wound made by a sharp-pointed instrument.

ably beautiful; and one with striped flowers. 2. The nana, or dwarf American pomegranate, rises with a shrubby stem branching four or five feet high, with narrow short leaves and small red flowers, succeeded by small fruit; begins flowering in June and continues till October.

Culture. Both these species are propagated by layers: the young branches are to be chosen for this purpose, and autumn is the proper time for laying them. Those of the common sort may be trained either as half or full standards, or as dwarfs. But those designed for walls must be managed as directed for peaches.

Uses. The dried flowers of the double-flowered pomegranate are possessed of an astringent quality; for which reason they are recommended in diarrhoeas, dysenteries, &c. where astringent medicines are proper. The rind of the fruit is also a strong astringent, and as such is occasionally made use of.

PUNISHMENT, in law, the penalty which a person incurs on the commission of a crime. See the article *CRIME and Punishment*.

The ingenuity of men has been much exerted to torment each other; but the following are the punishments that have been usually adopted in the different countries of the world. The capital punishments have been beheading, crucifixion, burning, roasting, drowning, scalping, hanging by the neck, the arm, or the leg, starving, sawing, exposing to wild beasts, rending asunder by horses drawing opposite ways, burying alive, shooting, blowing from the mouth of a cannon, compulsory deprivation of sleep, rolling in a barrel stuck with nails pointed inwards, poisoning, pressing slowly to death by a weight laid on the breast, casting headlong from a rock, tearing out the bowels, pulling to pieces with red-hot pincers, the rack, the wheel, impaling, fleaing alive, &c. &c.

The punishments short of death have been, fine, pillory, imprisonment, compulsory labour at the mines, galleys, highways, or correction-house; whipping, bastonading, mutilation by cutting away the ears, the nose, the tongue, the breasts of women, the foot, the hand; squeezing the marrow from the bones with screws or wedges, castration, putting out the eyes, banishment, running the gauntlet, drumming, shaving off the hair, burning on the hand or forehead, &c.

PUNNING. See **PUN**.

PUPIL, in the civil law, a boy or girl not yet arrived at the age of puberty; i. e. the boy under 14 years, the girl under 12.

PUPIL is also used in universities, &c. for a youth under the education or discipline of any person.

PUPIL, in anatomy, a little aperture in the middle of the uvea and iris of the eye, through which the rays of light pass to the crystalline humour, in order to be painted on the retina, and cause vision. See **ANATOMY**, p. 765, &c.

PURCELL (Henry), a justly celebrated master of music, began early to distinguish himself. As his genius was original, it wanted but little forming; and he rose to the height of his profession with more ease than others pass through their rudiments. He was made organist to Westminster abbey in the latter end of the reign of Charles II. In that of William, he set several songs for Dryden's *Amythyrion* and his *King Arthur*, which were received with just applause. His notes on

his operas were admirably adapted to his words, and so echoed to the sense, that the sounds alone seemed capable of exciting those passions which they never failed to do in conjunction. His music was very different from the Italian. It was entirely English, and perfectly masculine. His principal works have been published under the title of *Orpheus Britannicus*. He died in 1695, in the 37th year of his age; and was interred in Westminster abbey, where a monument is erected to his memory.

PURCHAS (Samuel), an English divine, famous for compiling a valuable collection of voyages, was born in 1577, at Thacksted in Essex. After studying at Cambridge, he obtained the vicarage of Eastwood in his native county; but leaving that cure to his brother, he settled in London, in order to carry on the great work in which he was engaged. He published the first volume in folio 1613, and the four last, 12 years after, under the title of *Purchas his Pilgrimage, or Revelations of the world, and the Religions observed in all ages and places*. Meanwhile he was collated to the rectory of St Martin's, Ludgate, in London, and made chaplain to Dr Abbot, archbishop of Canterbury. His *Pilgrimage* and the learned Hackluyt's *Voyages*, led the way to all the other collections of that kind, and have been justly valued and esteemed. But unhappily, by his publishing, he involved himself in debt: however, he did not die in prison, as some have asserted; but at his own house, about the year 1628.

PURCHASE, in law, the buying or acquiring of lands, &c. with money, by deed or agreement, and not by descent or right of inheritance.

PURCHASE, in the sea-language, is the same as *draw in*: thus, when they say, the captain purchases a-pace, they only mean, it draws in the cable a-pace.

PURE, something free from any admixture of foreign or heterogeneous matters.

PURFLEW, a term in heraldry, expressing ermins, peans, or any of the furs, when they compose a bordure round a coat of arms: thus they say, He beareth gules, a bordure, purflew, vairy; meaning, that the bordure is vairy.

PURGATION, the art of purging, scouring, or purifying a thing, by separating, or carrying off any impurities found therein. Thus,

In pharmacy, purgation, is the cleansing of a medicine by retrenching its superfluities. In chemistry, it is used for the several preparations of metals and minerals intended to clear them of their impurities, more usually called *purification* and *refining*. See **REFINING**.

In medicine, purgation is an excretory motion arising from a quick and orderly contraction of the fleshy fibres of the stomach and intestines, whereby the chyle, corrupted humours, and excrements lodged therein, are protruded further and further, and at length quite excluded the body by stool. See **MATERIA MEDICA**.

For the menstrual purgation of women, see **MENSES**. **PURGATION**, in law, signifies the clearing a person's self of a crime of which he is suspected and accused before a judge. This purgation is either canonical or vulgar. Canonical purgation is prescribed by the canon-law, and the form thereof in the spiritual court is usually thus: The person suspected takes his oath that he is innocent of the crime charged against him; and at the same

Purgative. same time brings some of his neighbours to make oath that they believe he swears truly. **Purgatory.** Vulgar purgation was anciently by fire or water, or else by combat, and was practised till abolished by the canons. See *BATTEL in law, ORDEAL, &c.*

PURGATIVE, or *PURGING Medicines*, medicaments which evacuate the impurities of the body by stool, called also *cathartics*.

PURGATORY, a place in which the just, who depart out of this life, are supposed to expiate certain offences which do not merit eternal damnation. Broughton has endeavoured to prove that this notion has been held by Pagans, Jews, and Mahometans, as well as by Christians; and that in the days of the Maccabees the Jews believed that sin might be expiated by sacrifices after the death of the sinner, cannot be questioned.

**Papist misrepresented and reprec-
sented.** Much abuse has been poured upon the church of Rome for her doctrine of purgatory, and many false representations have been made of the doctrine itself. The following view of it is taken from a work which is considered as a standard by the British Catholics. 1. Every sin, how slight soever, though no more than an idle word, as it is an offence to God, deserves punishment from him, and will be punished by him hereafter, if not cancelled by repentance here. 2. Such small sins do not deserve eternal punishment. 3. Few depart this life so pure as to be totally exempt from spots of this nature, and from every kind of debt due to God's justice. 4. Therefore few will escape without suffering something from his justice for such debts as they have carried with them out of this world; according to that rule of divine justice, by which he treats every soul hereafter according to its works, and according to the state in which he finds it in death. From these propositions, which the Papist considers as so many self-evident truths, he infers that there must be some third place of punishment; for, since the infinite goodness of God can admit nothing into heaven which is not clean and pure from all sin both great and small; and his infinite justice can permit none to receive the reward of bliss, who as yet are not out of debt, but have something in justice to suffer; there must of necessity be some place or state, where souls, departing this life, pardoned as to the eternal guilt or pain, yet obnoxious to some temporal penalty, or with the guilt of some venial faults, are purged and purified before their admittance into heaven. And this is what he is taught concerning purgatory. Which, though he knows not where it is, of what nature the pains are, or how long each soul is detained there; yet he believes, that those that are in this place, being the living members of Jesus Christ, are relieved by the prayers of their fellow members here on earth, as also by alms and masses offered up to God for their souls. And as for such as have no relations or friends to pray for them, or give alms, or procure masses for their relief; they are not neglected by the church, which makes a general commemoration of all the faithful departed in every mass, and in every one of the canonical hours of the divine office.

Such is the Popish doctrine of purgatory, which is built chiefly upon 2 Macc. xii. 43, 44, 45; St Matth. xii. 31, 32; and 1 Cor. iii. 15. By Protestants the books of Maccabees are not acknowledged to be inspired scripture; but if they were, the texts referred to would rather prove that there is no such place as purgatory, since Judas did not expect the souls departed to

VOL. XV.

reap any benefit from his sin-offering till the resurrection. Our Saviour, in St Luke, speaks of remission in *this world* and in the world to *come*; but surely neither of these is purgatory. The world to come is the state after the resurrection, and the remission spoken of is the sentence of absolution to be pronounced on the penitent from the seat of general judgment. In the obscure verse referred to in the epistle to the Corinthians, the apostle is, by the best interpreters, thought to speak of the difficulty with which Christians should be saved from the destruction of Jerusalem. Of the state of souls departed he cannot well be supposed to speak, as upon disembodied spirits fire could make no impression. We cannot help, therefore, thinking with the church of England, that "the Romish doctrine of purgatory is a fond thing, vainly invented, and grounded on no warranty of scripture;" but we must confess at the same time, that it appears to us to be a very harmless error, neither hostile to virtue nor dangerous to society. See *RESURRECTION*.

PURIFICATION, in matters of religion, a ceremony which consists in cleansing any thing from a supposed pollution or defilement.

The Pagans, before they sacrificed, usually bathed or washed themselves in water; and they were particularly careful to wash their hands, because with these they were to touch the victims consecrated to the gods. It was also customary to wash the vessel with which they made their libations. The Mahometans also use purifications previous to the duty of prayer; which are also of two kinds, either bathing, or only washing the face, hands, and feet. The first is required only in extraordinary cases, as after having lain with a woman, touched a dead body, &c. But lest so necessary a preparation for their devotions should be omitted, either where water cannot be had, or when it may be of prejudice to a person's health, they are allowed in such cases to make use of fine sand, or dust instead of it; and then they perform this duty by clapping their open hands on the sand, and passing them over the parts, in the same manner as if they were dipped in water.

There were also many legal purifications among the Hebrews. When a woman was brought to bed of a male child, she was esteemed impure for 40 days; and when of a female, for 60: at the end of which time she carried a lamb to the door of the temple to be offered for a burnt-offering, and a young pigeon or turtle for a sin-offering; and by this ceremony she was cleansed or purified.

PURIM, or *The Feast of Lots*, a solemn festival of the Jews, instituted in memory of the deliverance they received, by means of Mordecai and Esther, from Haman's wicked attempt to destroy them.

PURITAN, a name formerly given in derision to the dissenters from the church of England, on account of the profession to follow the pure word of God, in opposition to all traditions and human constitutions. It was likewise given in the primitive church to the Novatian schismatics, because they would never admit to communion any one who from dread of death had apostatized from the faith.

PURITY, the freedom of any thing from foreign admixture.

PURITY of Style. See *ORATORY*, p. 411, &c.

PURLIEU, signifies all that ground near any forest, which

Purification
||
Purlieu

Purlins
||
Purulent.

which being made forest by King Henry II. Richard I. and King John, was afterwards by perambulations and grants of Henry III. severed again from the same, and made purlieu; that is to say, pure and free from the laws of the forest.—The word is derived from the French *pur* “pure,” and *lieu* “place.”

PURLINS, in building, those pieces of timber that lie across the rafters on the inside, to keep them from sinking in the middle of their length.

By the act of parliament for rebuilding London, it is provided, that all purlins from 15 feet 6 inches to 18 feet 6 inches long, be in their square 9 inches and 8 inches; and all in length from 18 feet 6 inches to 21 feet 6 inches, be in their square 12 inches and 9 inches.

PURPLE, a colour composed of a mixture of red and blue. See *COLOUR-Making*, n° 29. and *DYING*, n° 92.

PURPURA, in natural history. See MUREX: where we have given an account of the Tyrian method of dying purple with a liquid extracted from the fish. It has been affirmed, however, that no such method was ever practised. “At Tyre (says Mr Bruce) I engaged two fishermen, at the expence of their nets, to drag in those places where they said shell-fish might be caught, in hopes to have brought out one of the famous purple-fish. I did not succeed; but in this I was, I believe, as lucky as the old fishers had ever been. The purple-fish at Tyre seems to have been only a concealment of their knowledge of cochineal; as, had they depended upon the fish for their dye, if the whole city of Tyre applied to nothing else but fishing, they would not have coloured 20 yards of cloth in a year.”

PURPURE, in heraldry. The colour so called, which signifies *purple*, is in engraving represented by diagonal lines, from the left to the right. See *HERALDRY*, p. 441. and Plate CCXXVII. fig. ii. n° 6.

It may serve to denote an administrator of justice, a lawgiver, or a governor equal to a sovereign: and, according to G. Leigh, if it is compounded with

Or,	it signifies	Riches.
Arg.		Quietness.
Gul.		Politics.
Az.		Fidelity.
Ver.		Cruelty.
Sab.		Sadness.

PURPUREUS. See CONVULVUS, n° 3.

PURRE, or PERKIN. See HUSBANDRY, n° 238.

PURSER, an officer aboard a man of war, who receives her victuals from the victualler, sees that it be well stowed, and keeps an account of what he every day delivers to the steward. He also keeps a list of the ship's company, and sets down exactly the day of each man's admission, in order to regulate the quantity of provisions to be delivered out, and that the paymaster or treasurer of the navy may issue out the debursemments, and pay off the men, according to his book.

PURSLAIN, in botany. See PORTULACA.

PURVIEW, a term used by some lawyers for the body of an act of parliament, or that part which begins with “Be it enacted &c.” as contradistinguished from the preamble.

PURULENT, in medicine something mixed with, or partaking of, pus or matter,

PUS, in medicine, a white or yellowish matter designed by nature for the healing and cementing of wounds and sores.

The origin and formation of pus is as much unknown as that of any other animal fluid. In an inaugural dissertation published at Edinburgh by Dr Hendy, the author supposes pus to be a secreted fluid. It has been thought by many, that pus is either a sediment from serum when beginning to putrefy, or that it is the same fluid inspissated by the heat of the body. But both these opinions are refuted by some experiments of our author, which show, that pus is much less inclined to putrefaction than serum, and the putrefaction of both is hastened by an addition of some of the red part of the blood. Some other experiments were made in order to try whether pus could be artificially produced. A thin piece of lamb's flesh, applied to an ulcer discharging laudable pus, and covered over with lead, did not assume the appearance of pus, but became fetid, and was much lessened. Serum, in its inflammatory and in its ordinary state, and lymph in different states, were applied to the same ulcer, which still discharged good pus; but none of these were converted into pus; on the contrary, they became very putrid.

In opposition to these arguments of our author, however, it may be alleged, that if pus was a secreted fluid, the vessels by which it was secreted would certainly be visible; but no such thing has ever been observed: on the contrary, it is certain that pus cannot be formed unless the air is excluded from the wound. These disputes, however, are of no great consequence: but in some cases it becomes a matter of real importance to distinguish pus from mucus; as thus we may be enabled to know whether a cough is consumptive, or merely catarrhus. See MUCUS. Mr Home, in a dissertation on the properties of pus, in which he avails himself of the experiments of Mr Hunter, as delivered in his *Physiological Lectures*, says, “that the characteristic of pus is its being composed of globules; and he thinks that the presence of globules seems to depend upon the pus being in a perfect state. It differs from the blood in the colour of the globules; in their not being soluble in water, which those of the blood are; and from the fluid in which they swim being coagulable by a solution of sal ammoniac, which serum is not.” Respecting the formation of pus, our author adopts the idea suggested by Mr Hunter, that the vessels of the part assume the nature of a gland, and secrete a fluid which becomes pus. Mr Home ascertains, by experiment, that pus, at its formation, is not globular, but a transparent fluid, of a consistence, in some sort, resembling jelly; and that the globules are formed while lying upon the surface of the sore; requiring, in some instances, while the influence of the external air is excluded, fifteen minutes for that purpose.

PUSTULE, a pimple, or small eruption on the skin full of pus; such as the eruptions of the small-pox.

PUTAMINEÆ, (from *putamen* “a shell,”) the name of the 25th order of Linnæus's fragments of a natural method; consisting of a few genera of plants allied in habit, whose fleshy seed-vessels or fruit is frequently covered with a hard woody shell. See *BOTANY*, p. 462.

PUTEOLI, (Livy, Strabo): a town of Campania; so

Pus
||
Puteoli.

Puteoli
Putrefac-
tion.
Swim-
burne's
Travels in
the two Si-
cilies.

so called either from its wells, there being many hot and cold springs thereabouts; or from its stench, *putor*, caused by sulphureous exhalations, (Varro, Strabo). It is now called *Puzzuoli*, and is pleasantly and advantageously situated for trade. In a very remote age, the Cumæans made it their arsenal and dockyard; and to this naval establishment gave the sublime appellation of *Dicæarchia* or *Just Power*.

The Romans were well aware of the utility of this port and took great pains to improve its natural advantages. Nothing remains of their works but a line of piers, built to break the force of a rolling sea: they are vulgarly called the *bridge of Caligula*, because that madman is said to have marched in triumph from *Puzzuoli* to *Baia* on a bridge; but his was a bridge of boats.

The ruins of its ancient edifices are widely spread along the adjacent hills and shores. An amphitheatre still exists entire in most of its parts, and the temple of Serapis offers many curious subjects of observation; half of its buildings are still buried under the earth thrown upon it by volcanical commotions, or accumulated by the crumbings of the hill; the inclosure is square, environed with buildings for priests and baths for vocaries; in the centre remains a circular platform, with four flights of steps up to it, vases for fire, a central altar, rings for victims, and other appendages of sacrifice, entire and not displaced; but the columns that held its roof have been removed to the new palace of *Caserta* (see *CASERTA*). Behind this round place of worship stand three pillars without capitals, part of the pronaos of a large temple; they are of cipolline marble, and at the middle of their height are full of holes eaten in them by the file-fish*.

The present city contains near 10,000 inhabitants, and occupies a small peninsula; the cathedral was a pagan temple, dedicated to the divinities that presided over commerce and navigation. E. Long. 14. 40. N. Lat. 41. 15.

In the neighbourhood of Puteoli are many relicks of ancient grandeur, of which none deserves more attention than the Campanian way paved with lava, and lined on each side with venerable towers, the repositories of the dead, which are richly adorned with stucco in the inside. This road was made in a most solid expensive manner by order of Domitian, and is frequently the subject of encomium in the poems of Statius.

PUTI CARAJA, in botany, is a genus of Indian plants, of which the characters, as given by Sir William Jones in the *Asiatic Researches*, vol. ii. p. 351. are these. The calyx is five cleft, the corolla has five equal petals, the pericarpium a thorny legumen and two seeds, the leaves oval and pinnated, and the stem armed. "The seeds (says the learned President) are very bitter, and perhaps tonic; since one of them, bruised and given in two dozes, will, as the Hindoos assert, cure an intermittent fever."

PUTORIUS, in zoology. See **MUSTELA**.

PUTREFACTION, one of the natural processes, directly opposite to the life of animals and vegetables, by which organized bodies are dissolved, and reduced to what may be called their *original elements*.

Putrefaction differs from chemical solution; because, in the latter, the dissolved bodies are kept in their state of solution by being combined with a certain agent from which they cannot easily be separated; but in pu-

trification, the agent which dissolves the body appears not to combine with it in any manner of way, but merely to separate the parts from each other.—It differs also from the resolution of bodies by distillation with violent fire; because, in distillation new and permanent compounds are formed, but by putrefaction every thing seems to be resolved into substances much more simple and indestructible than those which are the result of any chemical process.

The bodies most liable to putrefaction are those of animals and vegetables, especially when full of juices. Stones, though by the action of the weather they will moulder into dust, yet seem not to be subject to any thing like a real putrefaction, as they are not resolved into any other substances than sand, or small dust, which still preserves its lapideous nature. In like manner, vegetables of any kind, when deprived of their juices by drying, may be preserved for many ages without being subjected to any thing like a putrefactive process. The same holds good with respect to animals; the parts of which, by simple drying, may be preserved in a sound state for a much longer time than they could be without the previous exhalation of their juices.

Putrefaction is generally allowed to be a kind of fermentation, or rather to be the last stage of that process; which, beginning with the vinous fermentation, goes on through the acetous, to the stage of putridity, where it stops. It is argued, however, and seemingly not without a great deal of reason, that if putrefaction is a fermentation, it must necessarily be a kind distinct from either the vinous or acetous; since we frequently observe that it takes place where neither the vinous nor the acetous stages have gone before; of consequence, it must be, in some cases at least, entirely independent of and unconnected with them. In several other respects it differs so much from these processes, that it seems in some degree doubtful whether it can with propriety be called a *fermentation* or not. Both the vinous and acetous fermentations are attended with a considerable degree of heat: but in the putrefaction of animal matters especially, the heat is for the most part so small, that we cannot be certain whether there is any degree of it or not produced by the process. In cases, indeed, where the quantity of corrupting animal matter is very great, some heat may be perceived: and accordingly Dr Monro tells us, that he was sensible of heat on thrusting his hand into the flesh of a dead and corrupting whale. But the most remarkable difference between the putrefactive fermentation and that of the vinous and acetous kinds is, that the end of both these processes is to produce a new and permanent compound; but that of the putrefactive process is not to produce any new form, but to destroy, and resolve one which already exists into the original principles from which all things seem to proceed. Thus, the vinous fermentation produces ardent spirits; the acetous, vinegar: but putrefaction produces nothing but earth, and some effluvia, which, though most disagreeable, and even poisonous to the human body, yet, being imbibed by the earth and vegetable creation, give life to a new race of beings. It is commonly supposed, indeed, that volatile alkali is a production of the putrefactive process: but this seems liable to dispute. The vapour of pure volatile alkali is not hurtful to the human frame, but that of putrefying substances is exceedingly so; and, excepting in the case of urine, the

Putrefac-
tion.

* *Pholas*
Dactylus,
Lin.

Putrefac-
tion.

generation of volatile alkali in putrid substances is very equivocal. This substance, which produces more alkali than any other, is much less offensive by its putrid fetor than others; and all animal substances produce a volatile alkali on being exposed to the action of fire, of quicklime, or of alkaline salts. In these cases the volatile alkali is not supposed to be produced by the quicklime or fixed salt, but only to be extricated from a kind of ammoniacal salt pre-existing in the animal matters; the probability is the same in the other case, viz. that volatile alkali is not produced, but only extricated, from these substances by putrefaction.

The only thing in which the putrefactive fermentation agrees with the other kinds is, that in all the three there is an extrication of fixed air. In the putrefactive process, it has been thought that this escape of the fixed air deprives the body of its cohesion: and Dr Macbride has written a treatise, in which he endeavours to prove, that fixed air is the very power of cohesion itself, and that all bodies when deprived of their fixed air entirely lose their cohesion. According to this hypothesis, the cause of putrefaction is the escape of fixed air: but it is impossible to give a reason why fixed air after having so long remained in a body, and preserved its cohesion, should of a sudden begin to fly off without being acted upon by something else. To a similar objection the hypothesis of those is liable, who suppose putrefaction to be occasioned by the escape of phlogiston; for phlogiston is now known to be a chimera: and though it were a reality, it would not fly off without something to carry it off, any more than fixed air. Animalcules have been thought to be the cause of putrefaction: but if animal substances are covered so as to exclude the access of flies or other insects, no such animalcules are to be discovered though putrefaction has taken place; and indeed it requires little proof to convince us, that animals are produced in corrupted bodies only because such substances prove a proper nidus for the eggs of the parent insects.

To understand the true cause of putrefaction, we must take notice of the circumstances in which the process goes on most rapidly. These are, heat, a little moisture, and confined air. Extreme cold prevents putrefaction, as well as perfect dryness; and a free circulation of air carries off the putrid effluvia; a stagnation of which seems to be necessary for carrying on the process. It seems also to hold pretty generally, that putrefying bodies swell and become specifically lighter; for which reason the carcases of dead animals, after having sunk in water, rise to the top and float. This last phenomenon, as has been observed under the article BLOOD, n° 29. shows that these bodies have received a certain quantity of an elastic principle from the air, which thus swells them up to such a size. It may be said indeed, that this increase of size in putrefying bodies is owing only to the extrication of air within themselves: but this amounts to the same thing; for the air which exists internally in the body of any animal, is entirely divested of elasticity while it remains there, and only shows its elastic properties upon being extricated. The elastic principle which combines with the air fixed in the animal substance, therefore, must come from the external atmosphere; and consequently the agent in putrefaction must be the elastic principle of the atmosphere itself, probably the same with elementary fire,

But, granting this to be true, it is difficult to show why putrefaction should not take place in a living body as well as in a dead one; seeing the one is as much exposed to the action of the air as the other. This difficulty, however, is not peculiar to the present hypothesis; but will equally occur whatever we may suppose the cause of putrefaction to be. The difficulty seems to be a little cleared up by Dr Priestley, who shows, that, by means of respiration, the body is freed from many noxious effluvia which would undoubtedly destroy it; and by the retention of which, he thinks, a living body would putrefy as soon as a dead one. The way in which respiration prevents the putrefaction of the body, is evidently the same with that in which the wind prevents fish or flesh hung up in it from becoming putrid. The constant inspiration of the air is like a stream of that element continually blown upon the body, and that not only upon its surface, but into it; by which means putrefaction is prevented in those parts that are most liable to become putrid. On the other hand, the elastic principle received from the air by the blood*, by invigorating the powers of life, quickening the circulation, and increasing perspiration, enables the body to expel noxious particles from other parts of the body which cannot conveniently be expelled by the lungs.

This leads us to consider the reason why a free exposure to the air prevents the coming on of putrefaction, or why the confining of the putrid effluvia should be so necessary in this process. Here it will be proper to recollect, that putrefaction is a simple resolution of the body into earth, air, &c. of which it seems originally to have been composed. This resolution is evidently performed by an expansive power seemingly situated in every particle of the body. In consequence of this principle, the body first swells, then bursts, flies off in vapour, and its particles fall asunder from each other. The action of the putrefactive process, then, is analogous to that of fire, since these are the very properties of fire, and the very effects which follow the action of fire upon any combustible body. It is therefore exceedingly probable, that the agent in the air, which we have all along considered as the cause of putrefaction, is no other than fire itself; that is, the ethereal fluid expanding itself every where, as from a centre to a circumference. The force of the fluid, indeed, is much less in putrefaction than in actual ignition; and therefore the effects also take place in a much smaller degree, and require a much longer time: nevertheless, the same circumstances that are necessary for keeping up the action of fire, are also necessary for keeping up the putrefactive process. One of these is a free access of air, yet without too violent a blast; for as fire cannot burn without air, neither can it endure too much of it: thus a candle goes out if put under a receiver, and the air exhausted; and it will do the same if we blow violently upon it. In like manner, putrefaction requires a certain quantity of air, much less indeed than fire: and as it requires less to support it, so it can also endure much less air than fire; for a stream of air which would not put out a fire, will effectually prevent putrefaction. The cause of this in both is the same. Fire cannot burn because the vapour is carried off too fast; and thus the latent heat, which ought to support the flame §, is entirely dissipated. In like manner putrefaction is as certainly attended with

167.

an emission of azotic gas as fire is with an emission of flame. These gases contain a great quantity of latent heat †, or of the expansive principle already mentioned; and if these are carried off with greater rapidity than the heat of the atmosphere can produce them, the consequence must be, that an opposite principle to that which produces putrefaction, namely, a principle of cold, or condensation, instead of expansion, must take place, and the body cannot putrefy. That this must be the case, is evident from the property which all evaporations have of producing cold ‡; and it is well known that a brisk current of air promotes evaporation to a great degree. Hence also the reason is evident why bodies are preserved uncorrupted by cold; for thus the action of the expansive principle is totally overcome and suspended, so that none of its effects can be perceived.

Thus we may see, that one reason why an animal body does not putrefy while alive, is its ventilation, as we may call it, by respiration; and another is, the continual accession of new particles, less disposed to putrefy than itself, by the food and drink which is constantly taken in. But if either of these ways of preventing the commencement of this process are omitted, then putrefaction will take place as well in a living as in a dead body. Of the truth of this last fact we have innumerable instances. When air is infected with the putrid effluvia of marshes, and thus the natural effluvia are not carried off from the human body, but, on the contrary, some enter into it which are not natural to it, the most putrid diseases are produced. The same thing happens from the putrid effluvia of dead bodies. Of this we have a remarkable instance in the fever which took place in Germany in the war of 1755: one reason of which is said to have been an infection of the air by the vast numbers of people killed in battle, to which was added a calm in the atmosphere for a long time; the putrid effluvia being by this prevented from flying off*. When Mr Holwell with 145 others were

imprisoned in the black-hole at Calcutta, after passing a night in that dismal habitation, he found himself in a high putrid fever. When sailors in long voyages are obliged to feed upon putrid aliments; when, thro' stormy weather, they are much exposed to wet; in the one case the putrescent effluvia being kept from flying off, and in the other a greater quantity being thrown into the body than what it naturally contains, the scurvy, malignant fevers, &c. make their appearance (A). Neither can these diseases be removed without removing every one of the causes just now mentioned: for as putrid diseases will be the consequence of confined air, nastiness, &c. though the provisions be ever so good; so, on the other hand, if the provisions be bad, the best air, and most exact cleanliness, nay, the best medicines in the world, will be of no service; as hath been often observed in the scurvy.

From this account of the nature, cause, and method of preventing putrefaction by means of a current of air, we may easily see the reason why it does not take place in some other cases also. Bodies will not putrefy *in vacuo*, because there the atmosphere has not access to impart its elastic principle; and though in the vacuum itself the principle we speak of does undoubtedly exist, yet its action there is by far too weak to decompose the structure of an animal body. In extreme cold, the reason why putrefaction does not take place has been already shown. If the heat is extremely great, the process of ignition or burning takes place instead of putrefaction. If the body is very dry, putrefaction cannot take place, because the texture is too firm to be decomposed by the weak action of the elastic principle. Putrefaction may also be prevented by the addition of certain substances; but they are all of them such as either harden the texture of the body, and thus render it proof against the action of the elastic fluid, or, by dissolving its texture entirely, bring it into a state similar to what it would be brought by

Putrefac-
tion.

(A) This aeriform fluid, which is exhaled from animal bodies in a state of putrefaction, acts at certain times more powerfully than at others, and is indeed in one stage of the process infinitely more noxious than any other elastic fluid yet discovered. In the Gentleman's Magazine for August 1788, Dr St John, informs us, that he knew a Gentleman who, by slightly touching the intestines of a human body beginning to liberate this corrosive gas, was affected with a violent inflammation, which in a very short space of time extended up almost the entire length of his arm, producing an extensive ulcer of the most foul and frightful appearance, which continued for several months, and reduced him to a miserable state of emaciation. The same writer mentions a celebrated professor who was attacked with a violent inflammation of the nerves and fauces from which he with difficulty recovered, merely by stooping for an instant over a body which was beginning to give forth this deleterious fluid. Hence he infers, that the same gas modified or mixed, or united with others, may be the occasion of the plague, which has so often threatened to annihilate the human species. It is happy, however, for mankind that this particular stage of putrefaction continues but for a few hours; and, what may appear very remarkable, this destructive gas is not very disagreeable in smell, and has nothing of that abominable and loathsome fetor produced by dead bodies in a less dangerous state of corruption; but has a certain smell totally peculiar to itself, by which it may be instantly discovered by any one that ever smelled it before. This is an object very worthy the attention of physicians: it is both extremely interesting, and very little known; but at the same time it is a study in the highest degree unpleasant, from the detestable smell and nastiness which attend the putrefaction of animal bodies; and a man must be armed with uncommon philanthropy and resolution to attempt it.

Dr St John thinks it probable that there is a rapid fixation of the basis of vital air in dead bodies at a certain state of putrefaction on account of the luminous appearance which they sometimes make, and which exists but for a few hours: but whether this luminous appearance takes place in every body, or whether it precedes or follows the exhalations of the corrosive gas abovementioned, he had not, when he wrote his paper, been able to discover.

Putrefac-
tion.

by the utmost power of putrefaction; so that the process cannot then take place. Thus various kinds of salts and acids harden the texture of animal substances, and thus are successfully used as antiseptics. The same thing may be said of ardent spirits; while oils and gums of various kinds prove antiseptic by a total exclusion of air, which is necessary in some degree for carrying on the process of putrefaction. Many vegetables, by the astringent qualities they possess, harden the texture of animal substances, and thus prove powerfully antiseptic; while, on the other hand, fixed alkaline salts, quicklime, and caustic volatile alkali, though they prevent putrefaction, yet they do it by dissolving the substances in such a manner that putrefaction could do no more though it had exerted its utmost force. There is only one other antiseptic substance whose effects deserve to be considered, and that is sugar. This, tho' neither acid nor alkaline, is yet one of the most effectual means of preventing putrefaction: and this seems to be owing to its great tendency to run into the vinous fermentation, which is totally inconsistent with that of putrefaction; and this tendency is so great, that it can scarce be counteracted by the tendency of animal substances to putrefy in any circumstances whatever.

Some kinds of air are remarkably antiseptic, though this subject has not been so fully inquired into as could be wished. The most powerful of them in this respect is the nitrous air; next to it, is fixed air; but the powers of the other airs are not so well known. It is probable that the antiseptic properties of fixed and nitrous air, are owing to their quality of extinguishing fire, or at least that the principle is the same; but, till the nature of these two kinds of air are better known, little can be said with certainty on the subject.

Sir John Pringle has made experiments to determine the powers of certain substances to promote or to prevent putrefaction. From these experiments he has formed the following Table, showing the relative antiseptic powers of the saline substances mentioned. Having found that two drams of beef put in a phial with two ounces of water, and placed in a heat equal to 90° of Fahrenheit's thermometer, became putrid in 14 hours, and that 60 grains of sea-salt preserved a similar mixture of beef and water more than 30 hours, he made the antiseptic power of the sea-salt a standard, to which he compared the powers of the other salts. The algebraic character + signifies, that the substance to which it is annexed had a greater antiseptic power than is expressed by the numbers:

Sea-salt, or the standard	-	-	1
Sul-gem	-	-	1+
Vitriolated tartar	-	-	2
Spiritus Mindereri	-	-	2
Soluble tartar	-	-	2
Sal diureticus	-	-	2+
Crude Sal ammoniac	-	-	3
Saline mixture	-	-	3
Nitre	-	-	4+
Salt of hartshorn	-	-	4+
Salt of wormwood	-	-	4+
Borax	-	-	12
Salt of amber	-	-	20
Alum	-	-	30

N. B. The quantities of spiritus Mindereri and of

the saline mixture were such, that each of them contained as much alkaline salt as the other neutral salts.

Myrrh, aloes, asafœtida, and terra Japonica, were found to have an antiseptic power 30 times greater than the standard. Gum ammoniacum and sagapenum showed little antiseptic power.

Of all resinous substances, camphor was found to resist putrefaction most powerfully, Sir John Pringle believes that its antiseptic power is 300 times greater than that of sea-salt.

Chamomile flowers, Virginian snake root, pepper, ginger, saffron, contrayerva root, and galls, were found to be 12 times more antiseptic than sea-salt.

Infusions of large quantities of mint, angelica, ground ivy, green tea, red roses, common wormwood, mustard, and horse-radish, and also decoctions of poppy-heads, were more antiseptic than sea-salt.

Decoctions of wheat, barley, and other farinaceous grains, checked the putrefaction by becoming sour.

Chalk, and other absorbent powders, accelerated the putrefaction, and resolved meat into a perfect mucus. The same powders prevented an infusion of farinaceous grains from becoming mucilaginous and sour.

One dram of sea-salt was found to preserve two drams of fresh beef in two ounces of water, above 30 hours, uncorrupted, in a heat equal to that of the human body, or above 20 hours longer than meat is preserved in water without salt: but half a dram of salt did not preserve it more than two hours longer than pure water. Twenty-five grains of salt had little or no antiseptic quality. Twenty grains, 15 grains, but especially 10 grains only of sea-salt, were found to accelerate and heighten the putrefaction of two drams of flesh.—These small quantities of sea-salt did also soften the flesh more than pure water.

The same learned and ingenious physician made experiments to discover the effects of mixing vegetable with animal matters.

Two drams of raw beef, as much bread, and an ounce of water, being beat to the consistence of pap, and exposed to 90° of heat according to Fahrenheit's thermometer began to ferment in a few hours, and continued in fermentation during two days. When it began to ferment and swell, the putrefaction had begun; and in a few hours afterwards, the smell was offensive. Next day the putrid smell ceased, and an acid taste and smell succeeded. Flesh alimentary vegetables as spinach, asparagus, scurvy-grass, produced similar effects as bread on flesh, but in a weaker degree. From several other experiments he found, that animal substances excite the fermentation of vegetable substances, and that the latter substances correct the putrescency of the former.

By adding saliva to a similar mixture of flesh, bread, and water, the fermentation was retarded, moderated, but rendered of twice the usual duration, and the acid produced at last was weaker than when no saliva was used.

By adding an oily substance to the common mixture of flesh, bread, and water, a stronger fermentation was produced, which could not be moderated by the quantity of saliva used in the former experiment, till some fixed alkaline salt was added; which salt was found, without saliva, to stop suddenly very high fermentations.

He did not find that small quantities of the following salts,

Putrefac-
tion.

Putrefaction || **Puzzulana.** salts, sal ammoniac, nitre, vitriolated tartar, sal diureticus, salt of hartshorn, salt of wormwood, were septic, as small quantities of sea-salt were.

Sugar was found to resist putrefaction at first, as other salts do, and also to check the putrefaction after it had begun by its own fermentative quality, like bread, and other fermentative vegetables.

Lime-water made some small resistance to putrefaction.

Port-wine, small-beer, infusions of bitter vegetables, of bark, and the juice of antiscorbutic plants, retarded the fermentation of mixtures of flesh and bread. But an unstrained decoction of bark considerably increased that fermentation.

Crabs-eyes accelerated and increased the fermentation of a mixture of flesh and bread.

Lime-water neither retarded nor hastened the fermentation of such a mixture: but when the fermentation ceased, the liquor was neither putrid nor acid, but smelt agreeably.

Flesh pounded in a mortar was found to ferment sooner than that which had not been bruised.

The tough inflammatory crust of blood was found to be most putrescent; next to which the crassamentum, or red coagulated mafs; and lastly the serum.

Dr Macbride's experiments confirm many of those above related, especially those which show that the fermentation of vegetable substances is increased by a mixture of animal or putrescent matter; that the putrescency of the latter is corrected by the fermentative quality of the former; and that the putrefaction and fermentation of mixtures of animal and vegetable substances were accelerated by additions of absorbent earths and of Peruvian bark. He also found, that although unburnt calcareous earths were septic, quicklime and lime-water prevented putrefaction, but that they destroyed or dissolved the texture of flesh.

The experiments of the author of the *Essai pour servir à l'Histoire de la Putrefaction*, show that metallic salts, resinous powders, extracts of bark, and opium, are very powerfully antiseptic, and that salts with earthy bases are less antiseptic than any other salts.

PUTTOCK-SHROUDS. See *Puttock-Shrouds*.

PUTTY, in its popular sense, is a kind of paste compounded of whiting and lintseed oil, beaten together to the consistence of a thick dough.

It is used by glaziers for the fastening in the squares of glass in sash-windows, and by painters for stopping up the crevices and clefts in timber and wainscots, &c.

PUTTY sometimes also denotes the powder of calcined tin, used in polishing and giving the last gloss to works of iron and steel.

TERRA PUZZULANA, or **POZZOLANA**, is a greyish kind of earth used in Italy for building under water. The best is found about Puteoli, Baiæ, and Cumæ, in the kingdom of Naples, from the first of which places it derives its name. It is a volcanic product, composed of heterogeneous substances, thrown out from the burning mouths of volcanoes in the form of ashes; sometimes in such large quantities, and with so great violence, that whole provinces have been covered with it at a considerable distance. In the year 79 of the common era, the cities of Herculaneum, Pompeia, and Stabia, although at the distance of many miles from Vesuvius, were, nevertheless, buried under

the matters of these dreadful eruptions; as Bergman relates in his *Treatise of the Volcanic Products*. This volcanic earth is of a grey, brown, or blackish colour; of a loose, granular, or dusty and rough, porous or spongy texture, resembling a clay hardened by fire, and then reduced to a gross powder. It contains various heterogeneous substances mixed with it. Its specific gravity is from 2500 to 2800; and it is, in some degree, magnetic: it scarcely effervesces with acids, though partially soluble in them. It easily melts *per se*; but its most distinguished property is, that it hardens very suddenly when mixed with $\frac{1}{3}$ of its weight of lime and water; and forms a cement, which is more durable in water than any other.

According to Bergman's Analysis, 100 parts of it contain from 55 to 60 of siliceous earth, 20 of argillaceous, five or six of calcareous, and from 15 to 20 of iron. Its effects, however, in cement may perhaps depend only on the iron which has been reduced into a particular substance by means of subterraneous fires; evident signs of which are observable in the places where it is obtained. If the slate in Henneberg, or Kennekulle in the province of Westergotland, should happen to get fire, the uppermost stratum, which now consists of a mixture of iron and different kinds of rocks, called *graberg* in the account given of them, they might perhaps be changed partly into slag and partly into *terra puzzulana*.

It is evidently a martial argillaceous marl, that has suffered a moderate heat. Its hardening power arises from the dry state of the half-baked argillaceous particles, which makes them imbibe water very rapidly, and thus accelerates the desiccation of the calcareous part; and also from the quantity and semiphlogisticated state of the iron contained in it. It is found not only in Italy but in France, in the provinces of Auvergne and Limoges; and also in England and elsewhere.

PUZZUOLI. See **PUTEOLI**.

PYANEPSIA, in antiquity, an Athenian festival celebrated on the seventh day of the month *Pyanepsion*; which according to the generality of critics, was the same with our September.

Plutarch refers the institution of this feast to Theseus, who, after the funeral of his father, on this day paid his vows to Apollo, because the youths who returned with him safe from Crete then made their entry into the city. On this occasion, these young men putting all that was left of their provisions into one kettle, feasted together on it, and made great rejoicing. Hence was derived the custom of boiling pulse on this festival. The Athenians likewise carried about an olive branch, bound about with wool, and crowned with all sorts of first-fruits, to signify that scarcity and barrenness were ceased, singing in procession a song. And when the solemnity was over, it was usual to erect the olive-branch before their doors, as a preservative against scarcity and want.

PYCNOTYLE, in the ancient architecture, is a building where the columns stand very close to each other; only one diameter and a half of the column being allowed for the intercolumniations.

According to Mr Evelyn, the pycnostyle chiefly belonged to the composite order, and was used in the most magnificent buildings; as at present in the peristyle at St Peter's at Rome, which consists of near 300 columns;

Puzzulana ||
Pycnostyle.

Pygargus || **Pylus.** lumns; and in such as yet remain of the ancients, among the ruins of Palmyra.

PYGARGUS, in ornithology, a species of *FALCO*.

PYGMALION, in fabulous history, a king of Cyprus, who, being disgusted at the dissolute lives of the women of his island, resolved to live in perpetual celibacy; but making a statue of ivory, he fell so passionately in love with it, that the high festival of Venus being come, he fell down before the altar of that goddess, and besought her to give him a wife like the statue he loved. At his return home, he embraced, as usual, his ivory form, when he perceived that it became sensible by degrees, and was at last a living maid, who found herself in her lover's arms the moment she saw the light. Venus blessed their union; and, at the end of nine months, she was delivered of a boy, who was named *Paphos*.

PYGMY, a person not exceeding a cubit in height. This appellation was given by the ancients to a fabulous nation inhabiting Thrace; who brought forth young at five years of age, and were old at eight: these were famous for the bloody war they waged with the cranes. As to this story, and for the natural history of the true pygmy, see *SIMIA*.

PYKAR, a broker in India, inferior to those called *dallals*, who transacts the business at first hand with the manufacturer, and sometimes carries goods about for sale.

PYKE, a watchman in India, employed as a guard at night. Likewise a footman or runner on business. They are generally armed with a spear.

PYLADES, a son of Strophius, king of Phocis, by one of the sisters of Agamemnon. He was educated together with his cousin Orestes, with whom he formed the most inviolable friendship, and whom he assisted to revenge the murder of Agamemnon, by assassinating Clytemnestra and Ægisthus. He also accompanied him in Taurica Chersonesus; and for his services Orestes rewarded him, by giving him his sister Electra in marriage. Pylades had by her two sons, Medon and Strophius. The friendship of Orestes and Pylades became proverbial.

PYLORUS, in anatomy, the under orifice of the stomach. See *ANATOMY*, n° 91.

PYLUS (anc. geog.), a town of Elis; its ruins to be seen on the road from Olympia to Elis, (Pausanias); situated between the mouths of the Peneus and Sellees, near Mount Scollis, (Strabo.) Built by Pylas of Megara, and destroyed by Hercules, (Pausanias.)—Another Pylus in Triphylia, (Strabo); by which the Alpheus runs, (Pausanias); on the confines of Arcadia, and not in Arcadia itself, (id.)—A third in Messenia, (Strabo, Ptolemy); situated at the foot of Mount Ægæus on the sea-coast, over against the island Sphagea or Sphaeria: built by Pylas, and settled by a colony of Leleges from Megara; but thence expelled by Neleus and the Pelasgi, and therefore called *Nelea*, (Homer.) A sandy territory. The royal residence of Neleus, and of Nestor his son: the more ancient and more excellent Pylus; whence the proverb *Pylus ante Pylum*, (Aristophanes, Plutarch), used when we want to represent the arrogance and pride of any one: said to be afterwards called *Corymbasum*. It made a figure in the Peloponnesian war; for being rebuilt by the Athenians, it proved of great benefit to them for the space of 15

years, and of much annoyance to the Lacedæmonians, (Thucydides). All the three *Pyli* were subject to Nestor, (Strabo.)

PYRAMID, in geometry, a solid standing on a triangular, square, or polygonal basis, and terminating in a point at the top; or, according to Euclid, it is a solid figure, consisting of several triangles, whose bases are all in the same plane, and have one common vertex.

Pyramids are sometimes used to preserve the memory of singular events, and sometimes to transmit to posterity the glory and magnificence of princes. But as they are esteemed a symbol of immortality they are most commonly used as funeral monuments and temples to the gods. Such is that of Cælius at Rome; the pyramids of Dahur drawn by Pocock; and those other celebrated ones of Egypt, as famous for the enormity of their size as their antiquity. Of these the largest are the pyramids of *Geeza*, so called from a village of that name on the banks of the Nile, distant from them about 11 miles. The three which most attract the attention of travellers stand near one another on the west side of the river, almost opposite to Grand Cairo, and not far from the place where the ancient Memphis stood. They were visited by M. Savary, of whose description of them we shall here give an abstract.

He took his journey in the night-time, in order to get up to the top of the great one by sunrise. Having got within sight of the two great ones, while the full moon shone upon them, he informs us, that they appeared, at the distance of three leagues, like two points of rock crowned by the clouds.

It is in the rich territory which surrounds them that fable has placed the Elysian fields. The canals which intersect them are the Styx and Lethe.

"The aspects of the pyramids varied according to the circuits he made in the plain, and the position of the clouds displayed themselves more and more to view. At half past three in the morning we arrived (says he) at the foot of the greatest. We left our cloaths at the gate of the passage which leads to the inside, and descended, carrying each of us a flambeau in his hand. Towards the bottom you must creep like serpents to get into the interior passage, which corresponds with the former. We mounted it on our knees, supporting ourselves with our hands against the sides. Without this precaution one runs the risk of slipping on the inclined plane, where the slight notches are insufficient to stop the foot, and one might fall to the bottom. Towards the middle we fired a pistol, the frightful noise of which, repeated in the cavities of this immense edifice, continued a long time, and awakened thousands of bats, which flying round us, struck against our hands and faces, and extinguished several of our wax candles. They are much larger than the European bats. Arrived above, we entered a great hall, the gate of which is very low. It is an oblong square, wholly composed of granite. Seven enormous stones extend from one wall to the other, and form the roof. A sarcophagus made of a single block of marble lies at one end of it. It is empty; and the lid of it has been wrenched off. Some pieces of earthen vases lie around it. Under this beautiful hall is a chamber not so large, where you find the entrance to a conduit filled with rubbish. After examining these caves, where daylight never penetrated, we descended the same way, taking care not to fall in-

Pyramid.

Pyramid. to a well, which is on the left, and goes to the very foundations of the pyramid. Pliny makes mention of this well, and says it is 26 cubits deep. The internal air of this edifice never being renewed, is so hot and mephitic that one is almost suffocated. When we came out of it, we were dropping with sweat, and pale as death. After refreshing ourselves with the external air, we lost no time in ascending the pyramid. It is composed of more than 200 layers of stone. They overlap each other in proportion to their elevation, which is from two to four feet. It is necessary to climb up all these enormous steps to reach the top. We undertook it at the north-east angle, which is the least damaged. It took us, however, half an hour with great pains and many efforts to effect it.

"The sun was rising, and we enjoyed a pure air, with a most delicious coolness. After admiring the prospect around us, and engraving our names on the summit of the pyramid, we descended cautiously, for we had the abyss before us. A piece of stone detaching itself under our feet or hands might have sent us to the bottom.

"Arrived at the foot of the pyramid, we made the tour of it, contemplating it with a sort of horror. When viewed close, it seems to be made of masses of rocks; but at a hundred paces distance, the largeness of the stones is lost in the immensity of the whole, and they appear very small.

"To determine its dimensions is still a problem. From the time of Herodotus to our days it has been measured by a great number of travellers and learned men, and their different calculations, far from clearing up doubts, have only increased the uncertainty. The following table will serve at last to prove how difficult it is to come at the truth.

<i>Height of the great Pyramid.</i>		<i>Width of one of its sides.</i>	
Ancients.		French feet.	
Herodotus	- 800	-	- 800
Strabo	- 625	-	- 600
Diodorus Siculus	600 and a fraction.		700
Pliny	-	-	- 708
Moderns.			
Le Bruyn	- 616	-	- 704
Prosper Alpinus	625	-	- 750
Thevenot	- 520	-	- 682
Niebuhr	- 440	-	- 710
Greaves	- 444	-	- 648

Number of layers of Stone which form it.

Greaves	- 207	-	- layers.
Maillet	- 208	-	-
Albert Liewenstein	260		
Pococke	- 212	-	-
Belon	- 250	-	-
Thevenot	- 208	-	-

"It appears that Messrs Greaves and Niebuhr have prodigiously deceived themselves in measuring the perpendicular height of the great pyramid. All the travellers allow that it has at least 200 layers of stone. These layers are from two to four feet high. Accord-

VOL. XV.

ing to Pococke, they are from four feet and a half to four feet high, being not so high at the top as at the base. Prosper Alpinus informs us, that the elevation of the first layer is five feet, but it diminishes insensibly in proportion as one mounts. Thevenot mentions 208 steps of large stones, the thickness of which makes the height of them about two feet and a half one with another: He measured some of them more than three feet high. I have measured several of them which were more than three feet high, and I found none less than two; the least height of them we can take as a medium therefore is two feet and a half, which, even according to Mr Greaves's calculation, who reckons 207 layers, would make 517 feet 6 inches perpendicular height. Messrs Greaves, Maillet, Thevenot, and Pococke, who only differ in the number of the layers from 207 to 212, all mounted by the north-east angle, as the least injured. I followed the same route, and counted only 208 steps. But if we reflect that the pyramid has been open on the side next the desert, that the stones on that side have been thrown down, that the sand which covers them has formed a considerable hill, we shall not be astonished that Albert Liewenstein, Belon, and Prosper Alpinus, who must have mounted by the south-east or south-west angle, which are less exposed to the sands of Lybia, should have found a greater number of steps: so that the calculation of these travellers, agreeing with that of Diodorus Siculus and Strabo, appears to be nearest the true height of the pyramid taken at its natural base; whence we may conclude with reason that it is at least 600 feet high. Indeed this is authenticated by a passage of Strabo. These are his words: 'Towards the middle of the height of one of the sides is a stone that may be raised up. It shuts an oblique passage which leads to a coffin placed in the centre of the pyramid.' This passage, open in our days, and which in the time of Strabo was towards the middle of one face of the pyramid, is at present only 100 feet from the base. So that the ruins of the covering of the pyramid, and of the stones brought from within, buried by the sand, have formed a hill in this place 200 feet high. Pliny confirms this opinion. The great sphynx was in his time upwards of 62 feet above the surface of the ground. Its whole body is at present buried under the sand. Nothing more appears of it than the neck and head, which are 27 feet high. If even the sphynx, though defended by the pyramids against the northerly winds, which bring torrents of sand from Libya, be covered as high as 38 feet, what an immense quantity must have been heaped up to the northward of an edifice whose base is upwards of 700 feet long? It is to this we must attribute the prodigious difference between the accounts of the historians who have measured the great pyramid at distant periods, and at opposite angles. Herodotus, who saw it in the age nearest to its foundation, when its true base was still uncovered, makes it 800 feet square. This opinion appears very probable. Pliny also says that it covered the space of eight acres.

"Messrs Shaw, Thevenot, and the other travellers who pretend that this pyramid was never finished, because it is open and without coating, are in an error. It is only necessary to observe the remains of the mortar, with the splinters of white marble which are to be found in

4 R

many

Pyramid.

Pyramid.

many parts of the steps, to see that it has been coated. After reading attentively the description given of it by the ancients, every doubt vanishes, and the truth is as clear as day-light. Herodotus tells us, 'The great pyramid was covered with polished stones, perfectly well jointed, the smallest of which was 30 feet long. It was built in the form of steps, on each of which were placed wooden machines to raise the stones from one to another.' According to Diodorus, 'The great pyramid is built of stones, very difficult of workmanship, but of an eternal duration. It is preserved to our days (towards the middle of the Augustan age) without being in the least injured. The marble was brought from the quarries of Arabia.' 'This historian thought that the whole building was composed of stones, similar to those of the coating, which were of very hard marble. Had there been some pieces torn off, he would have perceived under that covering a calcareous stone rather soft. Pliny says that it 'is formed of stones brought from the quarries of Arabia. It is not far from the village of Busris (which still exists under the name of *Boufir*), where those persons reside who are so skilful as to climb up to the top.'

"This passage shows that Pliny, deceived by the appearance, was in the same error with Diodorus Siculus. It demonstrates also that it was covered: for what difficulty would there have been for the inhabitants of Busris to scale a building raised by steps? but it was really a prodigy for them to get up it when it formed a mountain, the four inclined planes of which presented a surface covered with polished marble. It is indeed an incontestable fact, that the great pyramid was coated. It is as certain too that it has been shut, as Strabo gives us to understand, and that by removing a stone placed in the middle of one of the sides, one found a passage which led to the tomb of the king. But I shall leave Mr Mailliet, who visited it 40 times with all imaginable attention, the honour of relating the means employed to open it. I have examined the inside of it in two different journeys: twice I have mounted it: and I cannot help admiring the sagacity with which that author has developed the mechanism of that astonishing edifice."

Our author next proceeds to give a particular description of the methods by which it is most probable that the pyramids were closed and the immense labour requisite to open them; but as this description affords nothing very interesting, we shall not insert it. Only we must remark, that the final outlet to the workmen he supposes to have been the well at the entrance formerly mentioned. This well descends towards the bottom of the pyramid by a line not quite perpendicular to the horizon, but slanting a little, in such a manner as to resemble the figure of the Hebrew letter Lamed. About 60 feet from the aperture there is a square window in this passage, from whence we enter a small grotto hewn out of the mountain; which in this place is not a solid stone, but a kind of gravel concreted together. The grotto extends about 15 feet from east to west, where there is another groove hollowed likewise, but almost perpendicular. It is two feet four inches wide by two and an half in height. It descends through a space of 123 feet, after which we meet with nothing but sand and stones. M. Savary is convinced that the only use of this passage was to serve as a retreat for the labourers who constructed the pyramid; and of this he looks

upon the slope of the conduit, its winding road, its smallness, and its depth, to be certain proofs. The way out of it he supposes to have been formed by a passage over which hung a row of stones, which they had discovered the secret of suspending, and which falling down into the passage by the means of some spring they set in motion, shut up the entrance for ever, as soon as the workmen were withdrawn from the pyramid.

It seems to be an unquestionable fact, that this pyramid was a mausoleum of one of the kings of Egypt, and it is very probable that all the rest answered similar purposes. We do not, however, think that this was their primary use or the original design of their builders. Mr Bryant is of opinion that they were temples erected in honour of the Deity; and a very ingenious writer in the Gentleman's Magazine for June 1794 has done much to prove that they were altars dedicated to the sun, the first and greatest god in every pagan calendar.

"Our English word pyramid (says he) is directly derived from the Latin *pyramis*, and mediately from the Greek *πυραμς*; all denoting the same mathematical figure. The original of the whole seems to be the Egyptian word *pyramoua*, which, we are told by Oriental scholars, signifies light, or a ray of light. From this Coptic vocable the word *πυρ* in Greek, signifying fire, is probably descended; as the flames of fire assume that conical or pyramidal form which the solar rays commonly display; and as it is natural for the mind to distinguish its objects rather by their external qualities, and those obvious and interesting appearances which they exhibit to the senses, than by their constituent and inseparable properties.

"The ancient Egyptians seem to have penetrated very far into the mysteries of nature; and although their superstition appears at first sight to be extremely gross and absurd, yet it is very probable that their deities were only emblematical personages, representing by sensible images the grand effects or presiding principles which they supposed to exist in the universe. Thus the moon was called *Ijs*, and the sun *Osiris*; and to the honour of this last deity, from whose visible influence and creative energy all things seem to spring into existence, it is not improbable that the Egyptians erected those stupendous monuments, and dedicated them to him as temples or altars. It was natural to build them in that shape which the rays of the sun display when discovered to the eye, and which they observed to be the same in terrestrial flame, because this circumstance was combined in their imaginations with the attribute which they adored. If they were temples dedicated to the sun, it seems a natural consequence that they should likewise be places of sepulture for kings and illustrious men, as the space which they covered would be considered as consecrated ground. This hypothesis is common, and is not contradicted by the present reasoning. But, considering them as altars, and as most travellers agree that they were never finished, but terminate in a square horizontal surface, it would not be refining too much to venture an assertion that, in great and solemn acts of adoration, the Egyptians constructed fires, the flames of which should terminate in the vertex of the pyramid, and so complete that emanation of their deity which they admired and adored. As far, therefore, as we are justified in forming any conclusion on so dark a subject,

Pyramid.

Pyramid. we may venture to say, that the Egyptian pyramids were temples or altars dedicated to the sun, as the material representative of that invisible power which creates, governs and pervades, the whole system of nature."

This reasoning has great force; and it certainly receives additional strength from the undoubted fact, that the first statues for idolatrous worship were erected on the tops of mountains, and of a pyramidal or conical form. (See POLYTHEISM, n° 13 and 21.) It is likewise corroborated by other circumstances discovered by the members of the Asiatic Society. In the second volume of their transactions we have an account of several large statues of the gods SEEVA and MCHEDO, all of a conical or pyramidal figure: but it has been shown in the article already referred to, that the idolatry of Hindostan was probably of Egyptian original.

It is not known in Europe when the pyramids were built; but we have reason to expect a history of them soon from Sanscrit records examined by Mr Wilford lieutenant of engineers. It is as little known at what time, or from what motive, the great pyramid was opened. Some think it was done by one of the khalifs about the beginning of the eighth century, in expectation of finding a great treasure; but all he met with was the king's body, with some golden idols which had been buried along with it.—By others it is supposed to have been done by the celebrated Harun Al Bafakid khalif of Bagdad; but all are agreed that this pyramid was opened in the time of the Arabs. The second pyramid has likewise been opened; and an attempt was made not long ago upon the third by one of the Beys of Cairo: but after removing a number of stones at a considerable expence, he thought proper to desist from the enterprize.—Mr Bryant is of opinion that the pyramids, at least the three great ones, are not artificial structures of stone and mortar, but solid rocks cut into a pyramidal shape, and afterwards cased with stone; and to this we find that Mr Bruce likewise assents. The reason given for this opinion is, that the passages within it seem rather to answer to the natural cavities and rents in rocks than to the artificial ones in buildings. The opinion, however, we think sufficiently confuted by Savary and Maillet: and, as an acute critic observes, it is in itself as improbable as that the caverns inhabited by the *Troglodytes* were dug by the hands of man. See TROGLODYTES.

On the east side of the second pyramid is the sphynx, an enormous mass of one solid stone, but so buried in the sand that only the top of the back is visible, which is 100 feet long. Its head rises, as we have seen, 27 feet above the sand; and its face has been disfigured by the Arabs, who hold all representations of men and living animals in detestation. Other travellers say that this sphynx is a huge misshapen rock, by no means worthy of the attention which has been bestowed upon it.

In the desert of Saccara there are a great number of pyramids, which, in Mr Bruce's opinion, are composed of clay. They terminate in what the inhabitants call a *dagour*, or *false pyramid*, about two miles from the Nile, between Suf and Woodan. This is no other than a hill cut into the shape of a pyramid, or naturally so formed, for a considerable height; on the top of which is a pyramidal building of brick terminating in a point, and having its basis so exactly adapted to the top of the hill, that at a distance the difference cannot be perceived; especially as the face of the stone resembles very

nearly the clay of which the pyramids of the Saccara are composed.

PYRAMIDALES, in anatomy, one of the muscles of the abdomen. See ANATOMY, *Table of the Muscles.*

PYRENEAN MOUNTAINS, or PYRENEES, are the mountains which divide France from Spain, and are the most celebrated in Europe, except the Alps. They reach from the Mediterranean Sea as far as the ocean, and are about 212 miles in length. They have different names, according to the different places wherein they stand. Some think they are as high as the Alps; but the passages over them are not so difficult, whatever some travellers may think who have not crossed the former.

BANKSIA PYRIFORMIS, in botany, is a species of BANKSIA, which see. It was unknown to Linnæus; and Gaertner, who has mentioned it, gives no specific character of it. It has solitary flowers, ovate downy capsules, and lance-shaped entire smooth leaves. The capsules larger than in any other known species. See *White's Journal of a Voyage to New South Wales*, p. 221—225.

PYRITES, a genus of inflammable substances composed of sulphur, which has dissolved or saturated itself with metals. Thus there are many kinds of pyrites; as of gold, arsenic, iron, &c. It is also the principal ore of sulphur; particularly that called *martial pyrites*, *copperas-stone*, or *marcasite*. This is very common, containing a quantity of sulphur in proportion to the iron; and, when thoroughly inflamed, burns by itself. It is either of a compact texture, steel-grained, coarse-grained, or crystallised. In this last form it shoots mostly into cube and octohedral figures, though it is met with also in innumerable other forms.

The liver-coloured marcasite has an appearance between that of the preceding and the blue copper-ore. The iron predominates in this kind, so that it is less fit than the other for extracting sulphur from it, or for the smelting of copper-ores. It is formed of a compact texture, coarse-grained, and steel-grained. See CHEMISTRY, n° 619 and 654; MINERALOGY, p. 109; and METALLURGY, p. 429.

PYRMONT, a town of Lippe in Germany, in the circle of Westphalia, and capital of a country of the same name. It has a castle, kept by a governor, who is under the counts of Waldeck. At a small distance from hence there are mineral waters, which are much esteemed. The Protestants have here the free exercise of their religion. It is seated on the confines of the duchy of Brunswick, 40 miles south-west of Hanover. E. Long. 9. 0. N. Lat. 52. 0.

PYROLA, in botany: A genus of the monogynia order, belonging to the decandria class of plants; and in the natural method ranking under the 18th order, *Bicornes*. The calyx is quinquepartite; there are five petals; the capsule is quinquelocular, opening at the angles.

PYROMANCY, a kind of divination by means of fire. See DIVINATION, n° 6.

PYROMETER, an instrument for measuring the expansion of bodies by heat. See CHEMISTRY, n° 103. Muschenbroeck, who was the original inventor of this machine, has given a table of the expansion of the different metals in the same degree of heat. Having prepared cylindric rods of iron, steel, copper, brass, tin,

Pyrometer. and lead, he exposed them first to a pyrometer with one flame in the middle ; then with two flames ; and successively to one with three, four, and five flames. But previous to this trial, he took care to cool them equally, by exposing them some time upon the same stone, when it began to freeze, and Fahrenheit's thermometer was at 32 degrees. The effects of which experiment are digested in the following table, where the degrees of expansion are marked in parts equal to the $\frac{1}{127}$ part of an inch.

Expansion of	Iron.	Steel.	Copper.	Brass.	Tin.	Lead.
By one flame	80	85	89	110	153	155
By two flames placed close together.	117	123	115	220		274
By two flames $2\frac{1}{2}$ inches distant.	109	94	92	141	219	263
By three flames placed close together.	142	168	193	275		
By four flames placed close together.	211	270	270	361		
By five flames.	230	310	310	377		

It is to be observed of tin, that it will easily melt when heated by two flames placed together. Lead commonly melts with three flames placed together, especially if they burn long.

From these experiments, it appears at first view that iron is the least rarefied of any of these metals, whether it be heated by one or more flames ; and therefore is most proper for making machines or instruments which we would have free from any alterations by heat or cold, as the rods of pendulums for clocks, &c. So likewise the measures of yards or feet should be made of iron, that their length may be as nearly as possible the same summer and winter.

The expansion of lead and tin, by only one flame, is nearly the same ; that is, almost double of the expansion of iron. It is likewise observable, that the flames placed together, cause a greater rarefaction than when they have a sensible interval between them ; iron in the former case, being expanded 117 degrees, and only 109 in the latter ; the reason of which difference is obvious.

By comparing the expansions of the same metal produced by one, two, three, or more flames, it appears that two flames do not cause double the expansion of one, nor three flames three times that expansion, but always less ; and these expansions differ so much the more from the ratio of the number of flames as there are more flames acting at the same time.

It is also observable, that metals are not expanded equally at the time of their melting, but some more some less. Thus tin began to run when rarefied 219 degrees ; whereas brass was expanded 377 degrees, and yet was far from melting.

Pyrometer. Mr Ellicot found, upon a medium, that the expansion of bars of different metals, as nearly of the same dimensions as possible, by the same degree of heat, were as follow :

Gold, Silver, Brass, Copper, Iron, Steel, Lead,
73 103 95 89 60 56 149

The great difference between the expansions of iron and brass has been applied with good success to remedy the irregularities in pendulums arising from heat. See PENDULUM.

Mr Graham used to measure the minute alterations, in length, of metal bars, by advancing the point of a micrometer-screw, till it sensibly stopped against the end of the bar to be measured. This screw, being small and very lightly hung, was capable of agreeing within the three or four-thousandth part of an inch. On this general principle Mr Smeaton contrived his pyrometer, in which the measures are determined by the contact of a piece of metal with the point of a micrometer-screw.

The following table shows how much a foot in length of each metal grows longer by an increase of heat, corresponding to 180° of Fahrenheit's thermometer, or to the difference between freezing and boiling water, expressed in such parts of which the unit is equal to the 10,000th part of an inch.

We shall close this article with a brief description of a pyrometer lately invented by M. De Luc, in consequence of a hint suggested to him by Mr Ramsden. The basis of this instrument is a rectangular piece of deal-board two feet and a half long, 15 inches broad, and one inch and a half thick ; and to this all the other parts are fixed. This is mounted in the manner of a table, with four deal legs, each a foot long and an inch and a half square, well fitted near its four angles, and kept together at the other ends by four firm cross-pieces. This small table is suspended by a hook to a stand ; the board being in a vertical situation in the direction of its grain, and bearing its legs forward in such a manner as that the cross-pieces which join them may form a frame, placed vertically facing the observer. This frame sustains a microscope, which is firmly fixed in another frame that moves in the former by means of grooves, but with a very considerable degree of tightness ;

Pyrometer, nefs; the friction of which may be increased by the pressure of four screws. The inner sliding frame, which is likewise of deal, keeps the tube of the microscope in a horizontal position, and in great part without the frame, inasmuch that the end which carries the lens is but little within the space between the frame and the board. This microscope is constructed in such a manner as that the object observed may be an inch distant from the lens; and it has a wire which is situated in the focus of the glasses, in which the objects appear reversed. At the top of the apparatus there is a piece of deal, an inch and a half thick and two inches broad, laid in a horizontal direction from the board to the top of the frame. To this piece the rods of the different substances, whose expansion by heat is to be measured, are suspended: one end of it slides into a socket, which is cut in the thickness of the board; and the other end, which rests upon the frame, meets there with a screw, which makes the piece move backward and forward, to bring the objects to the focus of the microscope. There is a cork very strongly driven through a hole bored vertically through this piece; and in another vertical hole made through the cork, the rods are fixed at the top; so that they hang only, and their dilatation is not counteracted by any pressure. In order to heat the rods, a cylindrical bottle of thin glass, about 21 inches high, and four inches in diameter, is placed in the inside of the machine, upon a stand independent of the rest of the apparatus. In this bottle the rods are suspended at a little less than an inch distance from one of the insides, in order to have them near the microscope. Into this bottle is poured water of different degrees of heat, which must be stirred about, by moving upwards and downwards, at one of the sides of the bottle, a little piece of wood, fastened horizontally at the end of a stick: in this water is hung a thermometer, the ball of which reaches to the middle of the height of the rods. During these operations the water rises to the cork, which thus determines the length of the heated part; the bottle is covered, to prevent the water from cooling too rapidly at the surface; and a thin case of brass prevents the vapour from fixing upon the piece of deal to which the rods are fixed.

PYROPHORUS, formed of $\alpha\upsilon\rho$, fire, and $\phi\sigma\phi\omega$, I bear, in chemistry, the name usually given to that substance called by some black phosphorus; a chemical preparation possessing the singular property of kindling spontaneously when exposed to the air. See **CHEMISTRY**, n° 1414.

This substance was accidentally discovered by M. Homberg, who prepared it of alum and human feces. See **PHOSPHORUS**. It was apprehended, for a considerable time after the discovery, that human feces were essential to the operation, till the youngest son of the great Lemerî found that honey, sugar, flour, and indeed any animal or vegetable matter, might be substituted instead of the human feces; and since that time, M. De Sauvigny has shown that most vitriolic salts may be substituted for the alum; having added to the aluminous pyrophorus of Homberg two other classes of substances of this kind, viz. the metallic, or those made with the three vitriols of iron, copper, and zinc; and the neutral, or those composed of vitriolated tartar and Glauber's salt.

Mr Bewly prepares his pyrophorus in the following manner. "I fill (says he) half or three-fourths of the bowl of a tobacco-pipe with a mixture, consisting of two parts of alum, previously calcined in a red-heat, and of powdered charcoal and salt of tartar each one part; pressing the matter down slightly, and filling the remainder of the bowl with fine sand. As soon as the powder becomes hot, the sand lying over it is put into a state of ebullition, which generally continues several minutes. This appearance seems to proceed partly from the vitriolic acid in the alum leaving its earth, and expelling fixed air from the alkali; while another part of it is possibly converted into vitriolic acid air. This phenomenon is succeeded by the appearance of a blue sulphureous flame, proceeding from the combination of the same acid with what was formerly called the *phlogiston of the coal*, and which continues about ten minutes or a quarter of an hour. After it ceases, no other remarkable appearance presents itself. The matter is now to be kept in a red heat 20 minutes or half an hour; or it may continue there two hours longer, if the operator pleases, without any injury to the pyrophorus. The pipe being taken out of the fire, the matter is knocked out of it as soon as it becomes cool, and generally pretty soon afterwards takes fire spontaneously."

In another experiment, having added successively various and increasing quantities of fixed alkali to the salt heated as above, till the vitriolic acid contained in the mixture might be considered merely as an evanescent quantity, a pyrophorus was still produced on calcining it with charcoal as before. He also mixed equal parts of salt of tartar and vegetable or animal coal, or sometimes three parts of the former with two of the latter, and calcined them in the usual manner: and this composition, on being exposed to the air, generally kindled in half a minute or a minute; though, as it contained no sulphur, it did not burn with so much vivacity as the vitriolic pyrophori. This, which Mr Bewly calls the *alkaline pyrophorus*, differs in no circumstance from M. De Sauvigny's neutral pyrophori, except in its not containing that principle to which he ascribes their ascension. However, lest it might be suspected that the salt of tartar which he employed might accidentally contain vitriolated tartar, or vitriolic acid, he repeated the experiment with tartar calcined by himself, as well as with nitre fixed or alkali fixed by deflagration with charcoal, and with iron filings; and in all these cases with the same result. By diversifying in a like manner M. De Sauvigny's experiments on the metallic pyrophori, Mr Bewly found that none of the three vitriols, heated with charcoal alone, in his usual method, could produce a pyrophorus. And thus he found that the addition of an alkaline salt to the composition, which was a part of M. De Sauvigny's process, was essential to its success.

Treating in the usual manner equal parts of calcined green vitriol and charcoal, the powder, which contained no sulphur nor hepar sulphuris, did not acquire any of the properties of a pyrophorus. The vitriolic acid seemed to have been entirely dissipated, having no base to detain it, when dislodged from the metallic earth. The charcoal and calx of iron left in this process were calcined again, together with some salt of tartar: and a pyrophorus was produced, which exhibited indications of its containing a scarce perceptible portion

Pyroph.
rus.

Pyropho-
rus.

portion of hepar sulphuris. Thirty grains of crocus martis atringens were calcined with 15 grains of charcoal, and the same quantity of salt of tartar; and the mixture burnt spontaneously, though it contained no hepar sulphuris or vitriolic acid. Having by these experiments evinced that metallic pyrophori may be prepared without vitriolic acid, Mr Bewly proceeded to form an aluminous pyrophorus of the same kind. For this purpose he procured the earth of alum by a long and violent calcination; and examining a part of it, he found, by the usual tests, that it neither contained any sulphur, hepar sulphuris, nor alum undecomposed. This he considered as perfectly pure, though he afterwards found that it contained a small quantity of vitriolated tartar; and yet it repeatedly furnished a pyrophorus, as active as when alum itself is employed. From these and similar experiments, he infers, that the several kinds of pyrophori are not kindled by moisture, attracted by the vitriolic acid, as M. De Sauvigny has maintained: and his conclusion is farther confirmed by some experiments of Dr Priestley; from which it appears, that they are kindled in dry, nitrous, and what he calls deplogified air.

M. Proust, cited by Mr Bewly, describes a variety of new pyrophori, which neither contain vitriolic acid, nor seem likely to owe their accension to the attraction of humidity from the air. These principally consist of a coaly matter simply divided by metallic or other earths; such are the sediment left on the filter in preparing Goulard's extract, various combinations of tartar or its acid, or the acetous acid, with metals, calcareous earth, &c.

Mr Bewly, having evinced the insufficiency of M. De Sauvigny's theory, and discovered that the pyrophori are not kindled by moisture, attracted (merely) by the vitriolic acid, directed his attention to the nitrous acid, which Dr Priestley has shown to be a constituent part of atmospherical air, as the probable agent in the production of this phenomenon. The strong affinity which this acid has with phlogiston, and the heat, and even flame, which it is known to produce with certain inflammable matters, manifested that it was equal to the effect; and having excluded the vitriolic acid from having any essential concern in this operation, he suggests, either that the pyrophorus is kindled by moisture attracted by some of the other ingredients which compose it; or that it has the power of decomposing atmospherical air, by suddenly attracting its nitrous acid, and thereby generating a heat sufficient to kindle the phlogistic matter contained in it. This idea appeared plausible, when he farther considered that Dr Priestley produced the purest respirable air with this same acid combined with other principles; and that this as well as common air is diminished, and probably in part decomposed, in a variety of phlogistic processes. This ingenious writer concludes, upon the whole, from the experiments he hath made, that the pyrophorus seems to owe its singular property to its being a combination of earth or alkali with phlogiston: the vitriolic acid, when present, only occasionally increasing or diminishing the effect, according to circumstances. In the process of calcination, the earth or alkaline principle is not merely mixed, but actually, though loosely, combined with the phlogistic principle of the coal; so that the pyrophorus,

considering it in its most simple state, is only a perfectly dry phlogisticated alkali or earth. On these data, the phenomena may be explained in the two following methods; with respect particularly to the influence of moisture and heat upon the pyrophorus. Supposing either the alkaline or earthy principle to have a greater affinity to water than to the phlogiston with which either of them is united, they may, on being exposed to a moist atmosphere, attract the humidity, and thereby set the phlogistic principle at liberty; which may, in its turn, attract, and be ignited by, the supposed aerial acid; its strong affinity to which is well known:—or, if this hypothesis be rejected, the inflammable matter may be kindled, merely in consequence of the heat produced by the combination of the alkali, &c. with moisture.

Mr Keir gives the following description of a process for preparing a new pyrophorus which he has lately discovered: "I filled about five-sixths of the contents of a copper cylindrical box, which had a lid fitted to it, and which was three inches in diameter and two inches in depth, with saw-dust, which I pressed down; and I laid upon the saw-dust as much well-washed *plumbum corneum* as entirely filled the box, which I then covered with its lid. I placed the box on the coals of a chamber-fire, so that its bottom only should be in contact with the fuel, and I kept it on the fire till no more vapour seemed to issue at the joining of the lid. I then removed it from the fire; and while it was hot, I closed up the joining of the lid with sealing-wax, by which means the external air was excluded. After it had stood in the cold about ten hours, I opened the box; and the corneous lead, which was very white before the operation, was now rendered black by the vapour which had arisen from the saw-dust, and which was obliged to pass through the lead before it could escape. This black metallic mass was no sooner exposed to the air, than ignited sparks appeared, which spread more and more, while the lead was seen to revive in the form of minute globules, and the part which did not revive was changed into a yellow powder or calx of lead. It is to be observed, that before I opened the box, I placed it at the side of the fire, in order to melt the sealing-wax, to enable me to separate the lid. It is possible that this small degree of heat may be necessary, or conducive, to the accension. I ought also to acquaint you, that the preparation of this pyrophorus requires nicer attention than that of any which I am acquainted with. For a small excess of heat will revive the lead, which will spoil the experiment. Also, If any air be admitted through the joints of the vessels employed, the kindling property will be prevented by the absorption of the air; which in this case is generally too gradual to produce inflammation. The metallic substance in this state of impregnation with inflammable matter, although not a pyrophorus, is an exceeding quick tinder. For when touched, however slightly, by an ignited body, it will instantly kindle, and the fire will spread over the whole piece, reviving the lead wherever it goes, and exhibiting a very beautiful example of metallic reduction, not unlike the familiar experiment of reviving the lead of a wafer containing minium at the flame of a candle; but with this difference, that the fire in the wafer requires to be kept up by flame; whereas in this metallic tinder it spreads and creeps spontaneously along without flame over the mass.

Ingredients
and
Composi-
tions.

THE art of fire, or a science which teaches the management and application of fire in several operations. See FIRE, FURNACE, CHEMISTRY, DISTILLATION, METALLURGY, &c.

But the term is more particularly used to denote the doctrine of artificial fire-works and fire-arms teaching the structure and use, 1. Of those used in war, the attacking of fortifications, &c. for which see the articles FUSEE, GUN, GUNNERY, GUNPOWDER, MINE, &c.; and, 2. Of those made for amusement's sake, as rockets, stars, serpents, &c. the preparation and construction of which fall to be explained in the present article.

SECT. I. *Of Ingredients and Compositions.*1. *Saltpetre.*

Saltpetre being the principal ingredient in fire-works, and a volatile body, by reason of its aqueous and aerial parts, is easily rarefied by fire; but not so soon when foul and gross as when purified from its crude and earthy parts, which greatly retard its velocity: therefore, when any quantity of fire-works are to be made, it should be examined; for if it is not well cleansed, and of a good sort, your works will not have their proper effect; neither will it agree with the standing proportions of compositions. Therefore,

To refine it, put into a copper, or any other vessel, 100 lb. of rough nitre with 14 gallons of clean water; let it boil gently half an hour, and as it boils take off the scum; then stir it, and before it settles put it into your filtering bags, which must be hung on a rack, with glazed earthen pans under them, in which must be sticks laid across for the crystals to adhere to: it must stand in the pans two or three days to shoot; then take out the crystals, and let them dry. The water that remains in the pans boil again an hour, and strain it into the pans as before, and the saltpetre will be quite clear and transparent; if not, it wants more refining; to do which proceed as usual, till it is well cleansed of all its earthy parts.

N. B. Those who do not choose to procure their saltpetre by the above method, may buy it ready done, which for fire-works in general will do.

To pulverize Saltpetre. Take a copper kettle, whose bottom must be spherical, and put into it 14 lb. of refined saltpetre, with 2 quarts or 5 pints of clean water: then put the kettle on a slow fire; and when the saltpetre is dissolved, if any impurities arise, skim them off, and keep constantly stirring with two large spatulas, till all the water exhales; and when done enough, it will appear like white sand, and as fine as flour; but if it should boil too fast, take the kettle off the fire, and set it on some wet sand, which will prevent the nitre from sticking to the kettle. When you have pulverized a quantity of saltpetre, be careful to keep it in a dry place.

To extract Saltpetre from damaged Gunpowder.—Have some filtering bags, hung on a rack, with glazed earthen pans under them, in the same manner as those

for refining saltpetre; then take any quantity of damaged powder, and put it into a copper, with as much clean water as will cover it: when it begins to boil, take off the scum; and after it has boiled a few minutes, stir it up: then take it out of the copper with a small hand-kettle for that purpose, and put some into each bag, beginning at one end of the rack, so that by the time you have got to the last bag, the first will be ready for more. Continue thus till all the bags are full: then take the liquor out of the pans; which boil and filter, as before, two or three times, till the water run quite clear, which you must let stand in the pan some time, and the saltpetre will appear at top. To get the saltpetre entirely out of the powder, take the water from that already extracted, to which add some fresh and the dregs of the powder that remain in the bags, and put them in a vessel, to stand as long as you please: and when you want to extract the nitre, you must proceed with this mixture as with the powder at first, by which means you will draw out all the saltpetre; but this process must be boiled longer than the first.

2. *Sulphur, or Brimstone.*

Sulphur is one of the principal ingredients in gunpowder, and almost in all compositions of fire-works; and therefore great care must be taken of its being good, and brought to the highest perfection. To know when sulphur is good, you are to observe that it is of a high yellow; and if, when held in one's hand, it crackles and bounces, it is a sign that it is fresh and good: but as the method of reducing brimstone to a powder is very troublesome, it is better to buy the flour ready made, which is done in large quantities, and in great perfection; though when a grand collection of fire-works are to be made, the strongest and best sulphur is the lump brimstone ground in the manner directed in art. 8.

3. *Charcoal.*

Charcoal is a preservative by which the saltpetre and the brimstone are made into gunpowder, by preventing the sulphur from suffocating the strong and windy exhalation of the nitre. Charcoal for fire-works must always be soft and well burnt, which may be bought ready done.

4. *Gunpowder.*

See GUNPOWDER in the order of the alphabet. To grind or meal it, is directed in art. 8.

5. *Camphor.*

This may be had in the shops; and is of two kinds, differing in regard to the degree of their purity, and distinguished by the name of *rough* and *refined*. Refined camphor must be chosen of a perfectly clean white colour, very bright and pellucid, of the same smell and taste with the rough, but more acrid and pungent. It is so volatile, that merchants usually inclose it in lintseed, that the viscosity of that grain may keep its particles together.

6. *Benjamin.*

This is a resin found of different sorts; and distinguished by their colours, viz. yellow, grey, and brown; but the best is that which is easy to break, and full of white

Ingredient
and
Composi-
tions.

Captain
Jones's
Artificial
Fire-
works.

Ingredients and Compositions. white spots. It is one of the ingredients in odoriferous fire-works, when reduced to a fine flour; which may be done by putting into a deep and narrow earthen pot 3 or 4 oz. of benjamin grossly pounded; cover the pot with paper, which tie very close round the edge; then set the pot on a slow fire, and once in an hour take off the paper, and you will find some flour sticking to it, which return again in the pot; this you must continue till the flour appears white and fine. There is also an oil of benjamin, which is sometimes drawn from the dregs of the flour; it affords a very good scent, and may be used in wet compositions.

7. *Spur-fire.*

This fire is the most beautiful and curious of any yet known; and was invented by the Chinese, but now is in greater perfection in England than in China. As it requires great trouble to make it to perfection, it will be necessary that beginners should have full instructions; therefore care should be taken that all the ingredients are of the best, that the lamp-black is not damp and clodded, that the saltpetre and brimstone are thoroughly refined. This composition is generally rammed in 1 or 2 oz. cases about 5 or 6 inches long, but not drove very hard; and the cases must have their concave stroke struck very smooth, and the choke or vent not quite so large as the usual proportion: this charge, when driven and kept a few months, will be much better than when rammed; and will not spoil, if kept dry, in many years.

As the beauty of this composition cannot be seen at so great distance as brilliant fire, it has a better effect in a room than in the open air, and may be fired in a chamber without any danger: it is of so innocent a nature, that, though with an improper phrase, it may be called a *cold fire*; and so extraordinary is the fire produced from this composition, that, if well made, the sparks will not burn a handkerchief when held in the midst of them; you may hold them in your hand while burning, with as much safety as a candle; and if you put your hand within a foot of the mouth of the case, you will feel the sparks like drops of rain.—When any of these spur-fires are fired singly, they are called *artificial flower-pots*; but some of them placed round a transparent pyramid of paper, and fired in a large room, make a pretty appearance.

The composition consists of saltpetre 4 lb. 8 oz. sulphur 2 lb. and lamp-black 1 lb. 8 oz.; or, saltpetre 1 lb. sulphur $\frac{1}{4}$ lb. and lamp-black 4 quarts.—This composition is very difficult to mix. The saltpetre and brimstone must be first sifted together, and then put into a marble mortar, and the lamp-black with them, which you work down by degrees with a wooden pestle, till all the ingredients appear of one colour, which will be something greyish, but very near black: then drive a little into a case for trial, and fire it in a dark place; and if the sparks, which are called *stars*, or *pinks*, come out in clusters, and afterwards spread well without any other sparks, it is a sign of its being good, otherwise not; for if any drossy sparks appear, and the stars not full, it is then not mixed enough; but if the pinks are very small, and soon break, it is a sign that you have rubbed it too much.

This mixture, when rubbed too much, will be too fierce, and hardly show any stars; and, on the contrary, when not mixed enough, will be too weak, and

throw out an obscure smoke, and lumps of drops, without any stars. The reason of this charge being called the *spur-fire*, is because the sparks it yields have a great resemblance to the rowel of a spur, from whence it takes its name.

8. *To meal Gunpowder, Brimstone, and Charcoal.*

There have been many methods used to grind these ingredients to a powder for fire-works, such as large mortars and pestles made of ebony and other hard wood, and horizontal mills with brass barrels: but none have proved so effectual and speedy as the last invention, that of the mealing-table, represented in fig. 1. made of elm, with a rim round its edge 4 or 5 inches high; and at the narrow end A, is a slider that runs in a groove, and forms part of the rim: so that when you have taken out of the table as much powder as you can with the copper shovel (fig. 2.) sweep all clean out at the slider A. When you are going to meal a quantity of powder, observe not to put too much in the table at once; but when you have put in a good proportion, take the muller (fig. 3.) and rub it till all the grains are broke; then scarce it in a lawn sieve that has a receiver and top to it; and that which does not pass through the sieve, return again to the table, and grind it till you have brought it all fine enough to go through the sieve. Brimstone and charcoal are ground in the same manner, only the muller must be made of ebony; for these ingredients being harder than powder, would stick in the grain of elm, and be difficult to grind. As brimstone is apt to stick and clod to the table, it will be best to keep one for that purpose, by which means you will always have your brimstone clean and well ground.

2d 8. *To make Wheels and other Works incombustible.*

It being necessary, when your works are new, to paint them of some dark colour; therefore, if, instead of which, you make use of the following composition, it will give them a good colour, and in a great measure prevent their taking fire so soon as if painted. Take brick-dust, coal-ashes, and iron-filings, of each an equal quantity, and mix them with a double size, made hot. With this wash over your works, and when dry wash them over again; this will preserve the wood greatly against fire. Let the brick-dust and ashes be beat to a fine powder.

9. *To prepare Cast-iron for Gerbes, white Fountains, and Chinese Fire.*

Cast iron being of so hard a nature as not to be cut by a file, we are obliged to reduce it into grains, though somewhat difficult to perform; but if we consider what beautiful sparks this sort of iron yields, no pains should be spared to granulate such an essential material: to do which, get at an iron-foundry some thin pieces of iron, such as generally run over the mould at the time of casting: then have a square block made of cast iron, and an iron square hammer about four lb. weight; then, having covered the floor with cloth or something to catch the beatings, lay the thin pieces of iron on the block, and beat them with the hammer till reduced into a small grains; which afterwards scarce with a very fine sieve, to separate the fine dust, which is sometimes used in small cases of brilliant fire, instead of steel dust; and when you have got out all the dust, sift what remains with a sieve a little larger, and so on with sieves of different sizes, till

Ingredients and Compositions.

Plate
ccccxviii.

Ingredients
and Com-
positions.

till the iron passes through about the bigness of small bird-shot: your iron thus beat and sifted, put each fort into wooden boxes or oiled paper, to keep it from rusting. When you use it, observe the difference of its size, in proportion to the cases for which the charge is intended; for the coarse fort is only designed for very large gerbes of 6 or 8 lb.

10. Charges for Sky-rockets, &c.

Rockets of four ounces. Mealed powder 1 lb. 4 oz. saltpetre 4 oz. and charcoal 2 oz.

Rockets of eight ounces. I. Mealed powder 1 lb. saltpetre 4 oz. brimstone 3 oz. and charcoal 1½ oz. II. Meal-powder 1½ lb. and charcoal 4¼ oz.

Rockets of one pound. Meal-powder 2 lb. saltpetre 8 oz. brimstone 4 oz. charcoal 2 oz. and steel-filings 1½ oz.

Sky-rockets in general. I. Saltpetre 4 lb. brimstone 1 lb. and charcoal 1½ lb. II. Saltpetre 4 lb. brimstone 1½ lb. charcoal 1 lb. 12 oz. and meal-powder 2 oz.

Large sky-rockets. Salt-petre 4 lb. meal-powder 1 lb. and brimstone 1 lb.

Rockets of a middling size. I. Saltpetre 8 lb. sulphur 3 lb. meal-powder 3 lb. II. Saltpetre 3 lb. sulphur 2 lb. meal-powder 1 lb. charcoal 1 lb.

11. For Rocket Stars.

White stars. Meal-powder 4 oz. saltpetre 12 oz. sulphur vivum 6 oz. oil of spike 2 oz. and camphor 5 oz.

Blue Stars. Meal-powder 8 oz. saltpetre 4, sulphur 2, spirit of wine 2, and oil of spike 2.

Coloured or variegated stars. Meal-powder 8 drams, rochpetre 4 oz. sulphur vivum 2, and camphor 2.

Brilliant stars. Saltpetre 3½ oz. sulphur 1½, and meal-powder ¼, worked up with spirits of wine only.

Common stars. Saltpetre 1 lb. brimstone 4 oz. antimony 4½, isinglass ½, camphor ¼, and spirit of wine ¼.

Tailed stars. Meal powder 3 oz. brimstone 2, saltpetre 1, and charcoal (coarsely ground) ¼.

Drove stars. I. Saltpetre 3 lb. sulphur 1 lb. brimstone 12 oz. antimony 3. II. Saltpetre 1 lb. antimony 4 oz. and sulphur 8.

Fixed pointed stars. Saltpetre 8½ oz. sulphur 2, antimony 1 oz. 10 dr.

Stars of a fine colour. Sulphur 1 oz. meal-powder 1, saltpetre 1, camphor 4 dr. oil of turpentine 4 dr.

12. Rains.

Gold rain for sky rockets. I. Saltpetre 1 lb. meal-powder 4 oz. sulphur 4, brimstone 1, saw-dust 2¼, and glass-dust 6 dr. II. Meal-powder 12 oz. saltpetre 2, charcoal 4. III. Saltpetre 8 oz. brimstone 2, glass-dust 1, antimony ¾, brimstone ¼, and saw-dust 12 dr.

Silver rain. I. Saltpetre 4 oz. sulphur, meal-powder, and antimony, of each 2 oz. sal prunella ½ oz. II. Saltpetre ½ lb. brimstone 2 oz. and charcoal 4. III. Saltpetre 1 lb. brimstone ¼ lb. antimony 6 oz. IV. Saltpetre 4 oz. brimstone 1, powder 2, and steel-dust ¼ oz.

13. Water Rockets.

I. Meal-powder 6 lb. saltpetre 4, brimstone 3, charcoal 5. II. Saltpetre 1 lb. brimstone 4¼ oz. charcoal 6. III. Saltpetre 1 lb. brimstone 4 oz. charcoal 12. IV. Saltpetre 4 lb. brimstone 1½ lb. charcoal 1 lb. 12

Vol. XV.

oz. V. Brimstone 2 lb. saltpetre 4 lb. and meal-powder 4. VI. Saltpetre 1 lb. meal-powder 4 oz. brimstone 8½, charcoal 2. VII. Meal-powder 1 lb. saltpetre 3, brimstone 1; sea coal 1 oz. charcoal 8½, saw-dust ¼, steel-dust ½, and coarse charcoal ¼ oz. VIII. Meal-powder 1½ lb. saltpetre 3, sulphur 1½, charcoal 12 oz. saw-dust 2.

Sinking charge for water-rockets. Meal-powder 8 oz. charcoal ¼ oz.

14. Of Wheels.

Wheel cases from two ounces to four pounds. I. Meal-powder 2 lb. saltpetre 4 oz. iron-filings 7. II. Meal-powder 2 lb. saltpetre 12 oz. sulphur 4, steel-dust 3. III. Meal powder 4 lb. saltpetre 1 lb. brimstone 8 oz. charcoal 4½. IV. Meal-powder 8 oz. saltpetre 4, saw-dust ¼, sea-coal ¼. V. Meal-powder 1 lb. 4 oz. brimstone 4 oz. 10 dr. saltpetre 8 oz. glass-dust 2½. VI. Meal-powder 12 oz. charcoal 1, saw-dust, ¼. VII. Saltpetre 1 lb. 9 oz. brimstone 4 oz. charcoal 4½. VIII. Meal-powder 2 lb. saltpetre 1, brimstone ½, and sea-coal 2 oz. IX. Saltpetre 2 lb. brimstone 1, meal-powder 4, and glass-dust 4 oz. X. Meal-powder 1 lb. saltpetre 2 oz. and steel-dust 3½. XI. Meal-powder 2 lb. and steel-dust 2½ oz. with 2½ of the fine dust of beat iron. XII. Saltpetre 2 lb. 13 oz. brimstone 8 oz. and charcoal.

Slow fire for wheels. I. Saltpetre 4 oz. brimstone 2, and meal-powder 1½. II. Saltpetre 4 oz. brimstone 1, and antimony 1 oz. 6 dr. III. Saltpetre 4½ oz. brimstone 1 oz. and mealed powder 1½.

Dead fire for wheels. I. Saltpetre 1½ oz. brimstone, lapis-calaminaris ¼, and antimony 2 dr.

15. Standing or fixed Cases.

I. Meal-powder 4 lb. saltpetre 2, brimstone and charcoal 1. II. Meal-powder 2 lb. saltpetre 1, and steel-dust 8 oz. III. Meal-powder 1 lb. 4 oz. and charcoal 4 oz. IV. Meal powder 1 lb. and steel-dust 4 oz. V. Meal-powder 2½ lb. brimstone 4 oz. and sea-coal 6. VI. Meal-powder 3 lb. charcoal 5 oz. and saw-dust 1½.

16. Sun Cases.

I. Meal-powder 8½ lb. saltpetre 1 lb. 2 oz. steel-dust 2 lb. 10 oz. brimstone 4. II. Meal-powder 3 lb. saltpetre 6 oz. and steel-dust 7½.

17. A brilliant Fire.

Meal-powder 11 lb. saltpetre 1, brimstone 4 oz. steel-dust 1½ lb.

18. Gerbes.

Meal-powder 6 lb. and beat-iron 2 lb. 1½ oz.

19. Chinese Fire.

Saltpetre 12 oz. meal-powder 2 lb. brimstone 1 lb. 2 oz. and beat iron 12 oz.

20. Tourbillons.

Charge for four-ounce Tourbillons. Meal-powder 2 lb. 4 oz. and charcoal 4½ oz.

Eight-ounce Tourbillons. Meal-powder 2 lb. and charcoal 4½ oz.

Large Tourbillons. Meal-powder 2 lb. saltpetre 1, brimstone 8 oz. and beat iron 8.

N. B. Tourbillons may be made very large, and of different coloured fires: only you are to observe, that the larger they are, the weaker must be the charge; and, on the contrary, the smaller, the stronger their charge.

Ingredients
and Com-
positions.

21. *Water Balloons.*

I. Saltpetre 4 lb. brimstone 2, meal-powder 2, antimony 4 oz. saw-dust 4, and glass-dust $1\frac{1}{4}$. II. Saltpetre 9 lb. brimstone 3 lb. meal-powder 6 lb. rosin 12 oz. and antimony 8 oz.

22. *Water Squibs.*

I. Meal-powder 1 lb. and charcoal 1 lb. II. Meal-powder 1 lb. and charcoal 9 oz.

23. *Mine Ports or Serpents.*

I. Meal-powder 1 lb. and charcoal 1 oz. II. Meal-powder 9 oz. charcoal 1 oz.

24. *Port-fires.*

For firing rockets, &c. I. Saltpetre 12 oz. brimstone 4 oz. and meal-powder 2 oz. II. Saltpetre 8 oz. brimstone 4 oz. and meal-powder 2 oz. III. Saltpetre 1 lb. 2 oz. meal powder $1\frac{1}{2}$ lb. and brimstone 10 oz. This composition must be moistened with one gill of lintseed oil. IV. Meal-powder 6 oz. saltpetre 2 lb. 2 oz. and brimstone 10 oz. V. Saltpetre 1 lb. 4 oz. meal-powder 4 oz. brimstone 5 oz. saw-dust 8 oz. VI. Saltpetre 8 oz. brimstone 2 oz. and meal-powder 2 oz.

For illuminations. Saltpetre 1 lb. brimstone 8 oz. and meal-powder 6 oz.

25. *Cones or spiral Wheels.*

Saltpetre $1\frac{1}{2}$ lb. brimstone 6 oz. meal-powder 14 oz. and glass-dust 14 oz.

26. *Crowns or Globes.*

Saltpetre 6 oz. brimstone 2 lb. antimony 4 oz. and camphor 2 oz.

27. *Air Balloon Fuzes.*

I. Saltpetre 1 lb. 10 oz. brimstone 8 oz. and meal-powder 1 lb. 6 oz. II. Saltpetre $1\frac{1}{2}$ lb. brimstone 8 oz. and meal-powder 1 lb. 8 oz.

28. *Serpents for Pots des Brins.*

Meal-powder 1 lb. 8 oz. saltpetre 12 oz. and charcoal 2 oz.

29. *Fire pumps.*

I. Saltpetre 5 lb. brimstone 1 lb. meal-powder $1\frac{1}{2}$ lb. and glass-dust 1 lb. II. Saltpetre 5 lb. 8 oz. brimstone 2 lb. meal-powder 1 lb. 8 oz. and glass-dust 1 lb. 8 oz.

30. *A slow white Flame.*

I. Saltpetre 2 lb. brimstone 3 lb. antimony 1 lb. II. Saltpetre $3\frac{1}{2}$ lb. fulphur $2\frac{1}{2}$ lb. meal-powder 1 lb. antimony $\frac{1}{2}$ lb. glass-dust 4 oz. brimstone 1 oz.

N. B. These compositions, driven $1\frac{1}{4}$ inch in a 1 oz. case, will burn one minute, which is much longer time than an equal quantity of any composition yet known will last.

31. *Amber Lights.*

Meal-powder 9 oz. amber 3 oz. This charge may be drove in small cases, for illuminations.

32. *Lights of another Kind.*

Saltpetre 3 lb. brimstone 1 lb. meal-powder 1 lb. antimony $10\frac{1}{2}$ oz. All these must be mixed with the oil of spike.

33. *A red fire.*

Meal-powder 3 lb. charcoal 12 oz. and saw-dust 8 oz.

34. *A common Fire.*

Saltpetre 3 lb. charcoal 10 oz. and brimstone 2 oz.

35. *To make an artificial Earthquake.*

Mix the following ingredients to a paste with water, and then bury it in the ground, and in a few hours the

earth will break and open in several places. The composition : sulphur 4 lb. and steel-dust 4 lb.

36. *Compositions for Stars of different Colours.*

I. Meal-powder 4 oz. saltpetre 2 oz. brimstone 2 oz. steel-dust $1\frac{1}{2}$ oz. and camphor, white amber, antimony, and mercury-sublimate, of each $\frac{1}{2}$ oz. II. Rochepetre 10 oz. brimstone, charcoal, antimony, meal-powder, and camphor, of each $\frac{3}{4}$ oz. moistened with oil of turpentine. These compositions are made into stars, by being worked to a paste with aqua vitæ, in which has been dissolved some gum-tragacanth; and after you have rolled them in powder, make a hole through the middle of each, and string them on quick-match, leaving about 2 inches between each. III. Saltpetre 8 oz. brimstone 2 oz. yellow amber 1 oz. antimony 1 oz. and powder 3 oz. IV. Brimstone $2\frac{1}{2}$ oz. saltpetre 6 oz. olibanum or frankincense in drops 4 oz. mastic, and mercury-sublimate, of each 4 oz. meal-powder 5 oz. white amber, yellow amber, and camphor, of each 1 oz. antimony and orpiment $\frac{1}{2}$ oz. each. V. Saltpetre 1 lb. brimstone $\frac{1}{2}$ lb. and meal-powder 8 oz. moistened with petrolio-oil. VI. Powder $\frac{1}{2}$ lb. brimstone and saltpetre, of each 4 oz. VII. Saltpetre 4 oz. brimstone 2 oz. and meal-powder 1 oz.

Stars that carry tails of sparks. I. Brimstone 6 oz. antimony crude 2 oz. saltpetre 4 oz. and rosin 4 oz. II. Saltpetre, rosin, and charcoal, of each 2 oz. brimstone 1 oz. and pitch 1 oz.

These compositions are sometimes melted in an earthen pan, and mixed with chopped cotton-match, before they are rolled into stars; but will do as well if wetted, and worked up in the usual manner.

Stars that yield some sparks. I. Camphor 2 oz. saltpetre 1 oz. meal-powder 1 oz. II. Saltpetre 1 oz. ditto melted $\frac{1}{2}$ oz. and camphor 2 oz. When you would make stars of either of these compositions, you must wet them with gum-water, or spirit of wine, in which has been dissolved some gum-arabic, or gum-tragacanth, that the whole may have the consistence of a pretty thick liquid; having thus done, take 1 oz. of lint, and stir it about in the composition till it becomes dry enough to roll into stars.

Stars of a yellowish colour. Take 4 oz. of gum-tragacanth or gum-arabic, pounded and sifted through a fine sieve, camphor dissolved in brandy 2 oz. saltpetre 1 lb. fulphur $\frac{1}{2}$ lb. coarse powder of glass 4 oz. white amber $1\frac{1}{2}$ oz. orpiment 2 oz. Being well incorporated, make them into stars after the common method.

Stars of another kind. Take 1 lb. of camphor, and melt it in a pint of spirit of wine over a slow fire; then add to it 1 lb. of gum-arabic that has been dissolved; with this liquor mix 1 lb. of saltpetre, 6 oz. of fulphur, and 5 oz. of meal-powder; and after you have stirred them well together, roll them into stars proportionable to the rockets for which you intend them.

37. *Colours produced by the different Compositions.*

As variety of fires adds greatly to a collection of works, it is necessary that every artist should know the different effect of each ingredient. For which reason, we shall here explain the colours they produce of themselves; and likewise how to make them retain the same when mixed with other bodies: as for example, sulphur

Ingredients
and Com-
positions.

Ingredients
and Com-
positions.

fulphur give a blue, camphor a white or pale colour, saltpetre a clear white-yellow, amber a colour inclining to yellow, sal-ammoniac a green, antimony a reddish, rosin a copper colour, and Greek-pitch a kind of bronze, or between red and yellow. All these ingredients are such as show themselves in a flame, viz.

White flame. Saltpetre, fulphur, meal-powder, and camphor; the saltpetre must be the chief part.

Blue flame. Meal-powder, saltpetre, and fulphur vivum; fulphur must be the chief: Or meal-powder, saltpetre, brimstone, spirit of wine, and oil of spike; but let the powder be the principal part.

Flame inclining to red. Saltpetre, fulphur, antimony, and Greek-pitch; saltpetre the chief.

By the above method may be made various colours of fire, as the practitioner pleases; for, by making a few trials, he may cause any ingredient to be predominant in colour.

38. *Ingredients that show in Sparks when rammed in choaked Cases.*

The set colours of fire produced by sparks are divided into 4 sorts, viz. the black, white, grey, and red. The black charges are composed of 2 ingredients, which are meal-powder and charcoal; the white of 3, viz. saltpetre, fulphur, and charcoal; the grey of 4, viz. meal-powder, saltpetre, brimstone, and charcoal; and the red of 3, viz. meal-powder, charcoal, and saw-dust.

There are, besides these four regular or set charges, two others, which are distinguished by the names of *compound* and *brilliant charges*; the compound being made of many ingredients, such as meal-powder, saltpetre, brimstone, charcoal, saw-dust, sea-coal, antimony, glass dust, brass dust, steel filings, cast iron, tanner's dust, &c. or any thing that will yield sparks; all which must be managed with discretion. The brilliant fires are composed of meal-powder, saltpetre, brimstone, and steel dust; or with meal-powder and steel filings only.

39. *Cotton Quick-match,*

Is generally made of such cotton as is put in candles, of several sizes, from 1 to 6 threads thick, according to the pipe it is designed for; which pipe must be large enough for the match, when made, to be pushed in easily without breaking it. Having doubled the cotton into as many threads as you think proper, coil it very lightly into a flat-bottomed copper or earthen pan; then put in the saltpetre and the liquor, and boil them about 20 minutes; after which coil it again into another pan, as in fig. 4. and pour on it what liquor remains; then put in some meal-powder, and press it down with your hands till it is quite wet; afterwards place the pan before the wooden frame (fig. 5.) which must be suspended by a point in the centre of each end; and place yourself before the pan, tying the upper end of the cotton to the end of one of the sides of the frame.

When every thing is ready, you must have one to turn the frame round, while you let the cotton pass through your hands, holding it very lightly, and at the same time keeping your hands full of the wet powder; but if the powder should be too wet to stick to the cotton, put more in the pan, so as to keep a continual supply till the match is all wound up; you may wind it as close on the frame as you please, so that

it do not stick together; when the frame is full, take it off the points, and sift dry meal-powder on both sides the match, till it appear quite dry: in winter the match will be a fortnight before it is fit for use; when it is thoroughly dry, cut it along the outside of one of the sides of the frame, and tie it up in skins for use.

N. B. The match must be wound tight on the frames.

The ingredients for the match, are, cotton 1 lb. 12 oz. saltpetre 1 lb. spirits of wine 2 quarts, water 3 quarts, isinglass 3 gills, and meal-powder 10 lb. To dissolve 4 oz. of isinglass, take 3 pints of water.

2d 39. *Touch-paper for capping of Serpents, Crackers, &c.*

Dissolve, in spirits of wine or vinegar, a little saltpetre; then take some purple or blue paper, and wet it with this liquor, and when dry it will be fit for use; when you paste this paper on any of your works, take care that the paste does not touch that part which is to burn. The method of using this paper is by cutting it into slips, long enough to go once round the mouth of a serpent, cracker, &c. When you paste on these slips, leave a little above the mouth of the case not pasted; then prime the case with meal-powder, and twist the paper to a point.

SECT. II. *Of Moulds, Cases, Mixture, Instruments, &c.*

40. *Rocket moulds.*

As the performance of rockets depends much on their moulds, it is requisite to give a definition of them and their proportions: They are made and proportioned by the diameters of their orifice, which are divided into = parts. Fig. 6. represents a mould made by its diameter AB: its height from C to D is 6 diameters and 2 thirds; from D to E is the height of the foot, which is 1 diameter and 2 thirds; F the choak or cylinder, whose height is 1 diameter and 1-3d; it must be made out of the same piece as the foot, and fit tight in the mould; G an iron pin that goes through the cylinder to keep the foot fast; H the nipple, which is $\frac{1}{2}$ a diameter high, and 2-3ds thick, and of the same piece of metal as the former I, whose height is $3\frac{1}{4}$ diameters, and at the bottom is 1-3d of the diameter thick, and from thence tapering to 1-6th of the diameter. The best way to fix the piercer in the cylinder is to make that part below the nipple long enough to go quite through the foot, and rivet at bottom. Fig. 7. is a former or roller for the cases, whose length from the handle is $7\frac{1}{4}$ diameters, and its diameter 2-3ds of the bore. Fig. 8. the end of the former, which is of the same thickness, and 1 diameter and 2-3ds long; the small part, which fits into the hole in the end of the roller when the case is pinching, is 1-6th and $\frac{1}{4}$ of the mould's diameter thick. Fig. 9. the first drift, which must be 6 diameters from the handle; and this, as well as all other rammers, must be a little thinner than the former, to prevent the facking of the paper when you are driving in the charge. In the end of this rammer is a hole to fit over the piercer: the line K marked on this is 2 diameters and 1-3d from the handle; so that, when you are filling the rocket, this line appears at top of the case: you must then take the 2d rammer (fig. 10.) which from the handle is 4 diameters,

Of Moulds,
Cafes, Mix-
ture, Instru-
ments, &c.

diameters, and the hole for the piercer is $1\frac{1}{2}$ diameter long. Fig. 11. is the short and solid drift which you use when you have filled the cafe as high as the top of the piercer.

Rammers must have a collar of brafs at the bottom, to keep the wood from spreading or splitting, and the same proportion must be given to all moulds, from 1 oz. to 6 lb. We mentioned nothing concerning the handles of the rammers; however, if their diameter be equal to the bore of the mould, and 2 diameters long, it will be a very good proportion: but the shorter you can use them, the better; for the longer the drift, the less will be the pressure on the composition by the blow given with the mallet.

Dimensions for Rocket Moulds, if the Rockets are rammed solid.

Weight of rockets.	Length of the moulds without their feet.	Interior diameter of the moulds.	Height of the nipples.
lb. oz.	Inches.	Inches.	Inches.
6 0	34,7	3,5	1,5
4 0	38,6	2,9	1,4
2 0	13,35	2,1	1,0
1 0	12,25	1,7	0,85
0 8	10,125	1,333, &c.	0,6
0 4	7,75	1,125	0,5
0 2	6,2	0,9	0,45
0 1	4,9	0,7	0,35
0 $\frac{1}{2}$	3,9	0,55	0,25
6 drams	3,5	0,5	0,225
4 drams	2,2	0,3	0,2

The diameter of the nipple must always be equal to that of the former.

The thickness of the moulds is omitted, being very immaterial, provided they are substantial and strong.

Our author advises those who make rockets for private amusement, not to ram them solid; for it requires a very skilful hand, and an expensive apparatus for boring them, which will be shown hereafter. Driving of rockets solid is the most expeditious method, but not so certain as ramming them over a piercer.

41. Moulds for Wheel-cafes or Serpens.

Fig. 12. represents a mould, in which the cafes are drove solid; L the nipple (A), with a point (B) at top, which, when the cafe is filling, serves to stop the neck, and prevent the composition from falling out, which without this point it would do; and, in consequence, the air would get into the vacancy in the charge, and at the time of firing cause the cafe to burst. These sort of moulds are made of any length or diameter, according as the cafes are required; but the diameter of the rollers must be equal to half the bore, and the rammers made quite solid.

42. To roll Rocket and other Cafes.

Sky-rocket cafes are to be made $6\frac{1}{2}$ of their exterior diameter long; and all other cafes that are to be

filled in moulds must be as long as the moulds, within half its interior diameter.

Of Moulds,
Cafes, Mix-
ture, Instru-
ments, &c.

Rocket cafes, from the smallest to 4 or 6 lb. are generally made of the strongest sort of cartridge paper, and rolled dry; but the large sort are made of pasted pasteboard. As it is very difficult to roll the ends of the cafes quite even, the best way will be to keep a pattern of the paper for the different sorts of cafes; which pattern should be somewhat longer than the cafe it is designed for, and on it marked the number of sheets required, which will prevent any paper being cut to waste. Having cut your papers of a proper size, and the last sheet for each cafe with a slope at one end, so that when the cafes are rolled it may form a spiral line round the outside, and that this slope may always be the same, let the pattern be so cut for a guide. Before you begin to roll, fold down one end of the first sheet, so far that the fold will go 2 or 3 times round the former: then, on the double edge, lay the former with its handle off the table; and when you have rolled on the paper within 2 or 3 turns, lay the next sheet on that part which is loose, and roll it all on.

Having thus done, you must have a smooth board, about 20 inches long, and equal in breadth to the length of the cafe. In the middle of this board must be a handle placed lengthwise. Under this board lay your cafe, and let one end of the board lie on the table; then press hard on it, and push it forwards, which will roll the paper very tight: do this three or four times before you roll on any more paper. This must be repeated every other sheet of paper, till the cafe is thick enough; but if the rolling board be drawn backwards, it will loosen the paper: you are to observe, when you roll on the last sheet, that the point of the slope be placed at the small end of the roller. Having rolled your cafe to fit the mould, push in the small end of the former F, about 1 diameter from the end of the cafe, and put in the end-piece within a little distance of the former; then give the pinching cord one turn round the cafe, between the former and the end-piece; at first pull easy, and keep moving the cafe, which will make the neck smooth, and without large wrinkles. When the cafes are hard to choak, let each sheet of paper (except the first and last, in that part where the neck is formed) be a little moistened with water: immediately after you have struck the concave stroke, bind the neck of the cafe round with small twine, which must not be tied in a knot, but fastened with two or three hitches.

Having thus pinched and tied the cafe so as not to give way, put it into the mould without its foot, and with a mallet drive the former hard on the end-piece, which will force the neck close and smooth. This done, cut the cafe to its proper length, allowing from the neck to the edge of the mouth half a diameter, which is equal to the height of the nipple; then take out the former, and drive the cafe over the piercer with the long rammer, and the vent will be of a proper size. Wheel-cafes must be drove on a nipple with a point to close

(A) The nipple and cylinders to bear the same proportion as those for rockets.

(B) A round bit of brafs, equal in length to the neck of the cafe, and flat at the top.

Of Moulds,
Cafes, Mix-
ture, Instru-
ments, &c.

close the neck, and make the vent of the size required ; which, in most cafes, is generally $\frac{1}{4}$ of their interior diameter. As it is very often difficult, when the cafes are rolled, to draw the roller out, you may make a hole through the handle, and put in it a small iron pin, by which you may easily turn the former round and pull it out, Fig. 17. shows the method of pinching cafes ; P a treddle, which, when pressed hard with the foot, will draw the cord tight, and force the neck as close as you please ; Q a small wheel or pully, with a groove round it for the cord to run in.

Cafes are commonly rolled wet, for wheels and fixed pieces ; and when they are required to contain a great length of charge, the method of making those cafes is thus : Your paper must be cut as usual, only the last sheet must not be cut with a slope : having your paper ready, paste each sheet on one side ; then fold down the first sheet as before directed : but be careful that the paste do not touch the upper part of the fold ; for if the roller be wetted, it will tear the paper in drawing it out. In pasting the last sheet, observe not to wet the last turn or two in that part where it is to be pinched ; for if that part be damp, the pinching cord will stick to it, and tear the paper ; therefore, when you choak those cafes, roll a bit of dry paper once round the cafe, before you put on the pinching cord ; but this bit of paper must be taken off after the cafe is choaked. The rolling board, and all other methods, according to the former directions for the rolling and pinching of cafes, must be used to these as well as all other cafes.

43. To make Tourbillon Cafes.

Those sort of cafes are generally made about 8 diameters long ; but if very large, 7 will be sufficient : tourbillons will answer very well from 4 oz. to 2 lb. but when larger there is no certainty. The cafes are best rolled wet with paste, and the last sheet must have a straight edge, so that the cafe may be all of a thickness : when you have rolled your cafes after the manner of wheel-cafes, pinch them at one end quite close ; then with the rammer drive the ends down flat, and afterwards ram in about 1-3d of a diameter of dried clay. The diameter of the former for these cafes must be the same as for sky-rockets.

N. B. Tourbillons are to be rammed in moulds without a nipple, or in a mould without its foot.

44. Balloon Cafes or Paper Shells.

First, you must have an oval former turned of smooth wood ; then paste a quantity of brown or cartridge paper, and let it lie till the paste has quite soaked through ; this done, rub the former with soap or grease, to prevent the paper from sticking to it ; then lay the paper on in small slips, till you have made it 1-3d of the thickness of the shell intended. Having thus done, set it to dry ; and when dry, cut it round the middle, and the two halves will easily come off : but observe, when you cut, to leave about 1 inch not cut, which will make the halves join much better than if quite separated. When you have some ready to join, place the valves even together, paste a slip of paper round the opening to hold them together, and let that dry ; then lay on paper all over as before, everywhere equal, excepting that end which goes downwards in the mortar which may be a little thicker than the rest ; for that part which receives the blow from the

powder in the chamber of the mortar consequently requires the greatest strength. When the shell is thoroughly dry, burn a round vent at top, with square iron, large enough for the fuze : this method will do for balloons from 4 inches 2-5ths, to 8 inches diameter ; but if they are larger, or required to be thrown a great height, let the first shell be turned of elm, instead of being made of paper.

For a balloon of 4 inches 2-5ths, let the former be 3 inches 1-8th diameter, and $5\frac{1}{2}$ inches long. For a balloon of $5\frac{1}{2}$ inches, the diameter of the former must be 4 inches, and 8 inches long. For a balloon of 8 inches, let the diameter of the former be 5 inches and 15-16ths, and 11 inches 7-8ths long. For a 10-inch balloon, let the former be 7 inches 3-16ths diameter, and $14\frac{1}{2}$ inches long. The thickness of a shell for a balloon of 4 inches 2-5ths, must be $\frac{1}{2}$ inch. For a balloon of $5\frac{1}{2}$ inches, let the thickness of the paper be 5-8ths of an inch. For an 8-inch balloon, 7-8ths of an inch. And for a 10-inch balloon, let the shell be 1 inch 1-8th thick.

Shells that are designed for stars only, may be made quite round, and the thinner they are at the opening, the better ; for if they are too strong, the stars are apt to break at the bursting of the shell : when you are making the shell, make use of a pair of calibres, or a round gage, so that you may not lay the paper thicker in one place than another ; and also to know when the shell is of a proper thickness. Balloons must always be made to go easy into the mortars.

Cafes for illumination Port-fires. These must be made very thin of paper, and rolled on formers, from 2 to 5-8ths of an inch diameter, and from 2 to 6 inches long : they are pinched close at one end, and left open at the other. When you fill them, put in but a little composition at a time, and ram it in lightly, so as not to break the cafe : 3 or 4 rounds of paper, with the last round pasted, will be strong enough for these cafes.

Cafes and moulds for common Port-fires. Common port-fires are intended purposely to fire the works, their fire being very slow, and the heat of the flame so intense, that, if applied to rockets, leaders, &c. It will fire them immediately. Port-fires may be made of any length, but are seldom made more than 21 inches long : the interior diameter of port-fire moulds should be 10-16ths of an inch, and the diameter of the former $\frac{1}{2}$ an inch. The cafes must be rolled wet with paste, and one end pinched, or folded down. The moulds should be made of brass, and to take in two pieces lengthwise ; when the cafe is in the two sides, they are held together by brass rings, or hoops, which are made to fit over the outside. The bore of the mould must not be made quite through, so that there will be no occasion for a foot. Those port-fires, when used, are held in copper sockets, fixed on the end of a long stick : these sockets are made like port-crayons, only with a screw instead of a ring.

45. Of mixing the Compositions.

The performance of the principal part of fire-works depends much on the compositions being well mixed ; therefore great care must be taken in this part of the work, particularly for the composition for sky-rockets. When you have 4 or 5 pounds of ingredients to mix, which is a sufficient quantity at a time (for a larger proportion

Of Moulds,
Cafes, Mix-
ture, Instru-
ments, &c.

Of Moulds, Cases, Mix-
ture, Instru-
ments, &c.

proportion will not do so well), first put the different ingredients together; then work them about with your hands, till you think they are pretty well incorporated: after which put them into a lawn sieve with a receiver and top to it; and if, after it is sifted, any remains that will not pass through the sieve, grind it again till fine enough; and if it be twice sifted, it will not be amiss; but the compositions for wheels and common works are not so material, nor need be so fine. But in all fixed works, from which the fire is to play regular, the ingredients must be very fine, and great care taken in mixing them well together; and observe, that in all compositions wherein are steel or iron filings, the hands must not touch; nor will any works which have iron or steel in their charge keep long in damp weather, unless properly prepared, according to the following directions.

46. *To preserve Steel or Iron filings.*

It sometimes may happen, that fire-works may be required to be kept a long time, or sent abroad; neither of which could be done with brilliant fires, if made with filings unprepared; for this reason, that the saltpetre being of a damp nature, it causes the iron to rust; the consequence of which is, that when the works are fired, there will appear but very few brilliant sparks, but instead of them a number of red and droffy sparks; and besides, the charge will be so much weakened, that if this was to happen to wheels, the fire will hardly be strong enough to force them round. But to prevent such accidents, prepare your filings thus: Melt in a glazed earthen pan some brimstone over a slow fire, and when melted throw in some filings; which keep stirring about till they are covered with brimstone: this you must do while it is on the fire; then take it off, and stir in very quick till cold, when you must roll it on a board with a wooden roller, till you have broke it as fine as corn powder; after which sift from it as much of the brimstone as you can. There is another method of preparing filings, so as to keep 2 or 3 months in winter; this may be done by rubbing them between the strongest sort of brown paper, which before has been moistened with lintseed oil.

N. B. If the brimstone should take fire, you may put it out, by covering the pan close at top: it is not of much signification what quantity of brimstone you use, so that there is enough to give each grain of iron a coat; but as much as will cover the bottom of a pan of about 1 foot diameter, will do for 5 or 6 pound of filings, or cast-iron for gerbes.

47. *To drive or ram Sky-rockets, &c.*

Rockets drove over a piercer must not have so much composition put in them at a time as when drove solid; for the piercer, taking up great part of the bore of the case, would cause the rammer to rise too high; so that the pressure of it would not be so great on the composition, nor would it be drove everywhere equal. To prevent this, observe the following rule: That for those rockets which are rammed over a piercer, let the ladle (c) hold as much composi-

tion as, when drove, will raise the drift $\frac{1}{2}$ the interior diameter of the case, and for those drove solid to contain as much as will raise it $\frac{1}{2}$ the exterior diameter of the case: ladders are generally made to go easy in the case, and the length of the scoop about $1\frac{1}{2}$ of its own diameter.

The change of rockets must always be drove 1 diameter above the piercer, and on it must be rammed 1-3d of a diameter of clay; through the middle of which bore a small hole to the composition, that, when the charge is burnt to the top, it may communicate its fire, through the hole, to the stars in the head. Great care must be taken to strike with the mallet, and with an equal force, the same number of strokes to each ladle-full of charge; otherwise the rockets will not rise with an uniform motion, nor will the composition burn equal and regular: for which reason they cannot carry a proper tail; for it will break before the rocket has got half way up, instead of reaching from the ground to the top, where the rocket breaks and disperses the stars, rains, or whatever is contained in the head. When you are ramming, keep the drift constantly turning or moving; and when you use the hollow rammers, knock out of them the composition now and then, or the piercer will split them. To a rocket of 4 oz. give to each ladle-full of charge 16 strokes; to a rocket of 1 lb. 28; to a 2-pounder, 36; to a 4-pounder, 42; and to a 6-pounder, 56: but rockets of a larger sort cannot be drove well by hand, but must be rammed with a machine made in the same manner as those for driving piles.

The method of ramming of wheel-cases, or any other sort, in which the charge is drove solid, is much the same as sky-rockets; for the same proportion may be observed in the ladle, and the same number of strokes given, according to their diameters, all cases being distinguished by their diameters. In this manner, a case, whose bore is equal to a rocket of 4 oz. is called a 4-oz. case, and that which is equal to an 8-oz. rocket an 8-oz. case, and so on, according to the different rockets.

Having taught the method of ramming cases in moulds, we shall here say something concerning those filled without moulds; which method, for strong pasted cases, will do extremely well, and save the expence of making so many moulds. The reader must here observe, when he fills any sort of cases, to place the mould on a perpendicular block of wood, and not on any place that is hollow; for we have found by experience, that when cases were rammed on driving benches, which were formerly used, the works frequently miscarried, on account of the hollow resistance of the benches, which oft jarred and loosened the charge in the cases; but this accident never happens when the driving blocks are used (D).

When cases are to be filled without moulds, proceed thus. Have some nipples made of brass or iron, of several sorts and sizes, in proportion to the cases, and to screw or fix in the top of the driving block; when you have fixed in a nipple, make, at about $1\frac{1}{2}$ inch

(c) A copper scoop with a wooden handle.

(D) A piece of hard wood in the form of an anvil block.

Of Moulds,
Cafes, Mix-
ture, Instru-
ments, &c.

inch from it, a square hole in the block, 6 inches deep and 1 inch diameter; then have a piece of wood, 6 inches longer than the cafe intended to be filled, and 2 inches square; on one side of it cut a groove almost the length of the cafe, whose breadth and depth must be sufficient to cover near $\frac{1}{2}$ the cafe; then cut the other end to fit the hole in the block, but take care to cut it so that the groove may be of a proper distance from the nipple; this half mould being made and fixed tight in the block, cut, in another piece of wood nearly of the same length as the cafe, a groove of the same dimensions as that in the fixed piece; then put the cafe on the nipple, and with a cord tie it and the 2 half-moulds together, and your cafe will be ready for filling.

The dimensions of the above-described half-moulds are proportionable for cafes of 8 ounces; but notice must be taken, that they differ in size in proportion to the cafes.

Note, The clay, mentioned in this article, must be prepared after this manner: Get some clay, in which there is no stones nor sand, and bake it in an oven till quite dry; then take it out and beat it to a powder, and afterwards sift it through a common hair-sieve, and it will be fit for use.

48. Proportion of Mallets.

The best wood for mallets is dry beech. If a person uses a mallet of a moderate size, in proportion to the rocket, according to his judgment, and if the rocket succeeds, he may depend on the rest, by using the same mallet; yet it will be necessary that cafes of different sorts be drove with mallets of different sizes.

The following proportion of the mallets for rockets of any size, from 1 oz. to 6 lb. may be observed; but as rockets are seldom made less than 1 oz. or larger than 6 lb. we shall leave the management of them to the curious; but all cafes under 1 oz. may be rammed with an oz. rocket mallet. Your mallets will strike more solid, by having their handles turned out of the same piece as the head, and made in a cylindrical form. Let their dimensions be worked by the diameters of the rockets: for example; let the thickness of the head be 3 diameters, and its length 4, and the length of the handle 5 diameters, whose thickness must be in proportion to the hand.

49. Proportion of Sky-rockets, and manner of heading them.

Fig. 13. represents a rocket complete without its stick, whose length from the neck is 5 diameters 1-6th: the cafes should always be cut to this length after they are filled. M is the head, which is 2 diameters high, and 1 diameter 1-6th $\frac{1}{2}$ in breadth; N the cone or cap, whose perpendicular height must be 1 diameter 1-3d. Fig. 14. the collar to which the head is fixed: this is turned out of deal or any light wood, and its exterior diameter must be equal to the interior diameter of the head; 1-6th will be sufficient for its thickness, and round the outside edge must be a groove; the interior diameter of the collar must not be quite so wide as the exterior diameter of the rocket; when this is to be glued on the rocket, you must cut two or three rounds of paper off the cafe, which will make a shoulder for it to rest upon. Fig. 15. a former for the head: two or three rounds of paper well pasted will be enough for the head, which, when rolled, put the collar on that part of the former marked O, which must fit the inside of

it; then, with the pinching cord pinch the bottom of the head into the groove, and tie it with small twine. Fig. 16. a former for the cone. To make the caps, cut your paper in round pieces, equal in diameter to twice the length of the cone you intend to make; which pieces being cut into halves, will make two caps each, without wasting any paper; having formed the caps, paste over each of them a thin white paper, which must be a little longer than the cone, so as to project about $\frac{1}{2}$ an inch below the bottom: this projection of paper, being notched and pasted, serves to fasten the cap to the head.

When you load the heads of your rockets, with stars, rains, serpents, crackers, scrolls, or any thing else, according to your fancy, remember always to put 1 ladle-full of meal-powder into each head, which will be enough to burst the head, and disperse the stars, or whatever it contains: when the heads are loaded with any sort of cafes, let their mouths be placed downwards; and after the heads are filled, paste on the top of them a piece of paper, before you put on the caps. As the size of the stars often differ, it would be needless to give an exact number for each rocket; but this rule may be observed, that the heads may be nearly filled with whatever they are loaded.

50. Decorations for Sky-rockets.

Sky-rockets bearing the pre-eminence of all fireworks, it will not be improper to treat of their various kinds of decorations, which are directed according to fancy. Some are headed with stars of different sorts, such as tailed, brilliant, white, blue, and yellow stars, &c.; some with gold and silver rain; others with serpents, crackers, firescrolls, marrons; and some with small rockets, and many other devices, as the maker pleases.

Dimensions and poise of Rocket-sticks.

Weight of the rocket.	Length of the stick.	Thickness at top.	Breadth at top.	Square at bottom.	Poise from the point of the cone.
L. oz.	F. in.	Inches.	Inches.	Inches.	F. in.
6 0	14 0	1,5	1,85	0,75	4 1,5
4 0	12 10	1,25	1,40	0,625	3 9,
2 0	9 4	1,125	1,	0,525	2 9,
1 0	8 2	0,725	0,80	0,375	2 1,
8	6 6	0,5	0,70	0,25	1 10,5
4	5 3	0,3750	0,55	0,35	1 8,5
2	4 1	0,3	0,45	0,15	1 3,
1	3 6	0,25	0,35	0,10	11 0,
$\frac{1}{2}$	2 4	0,125	0,20	0,16	8 0,
$\frac{1}{4}$	1 10 $\frac{1}{2}$	0,1	0,15	0,5	5 0,5

The last column on the right, in the above table, expresses the distance from the top of the cone, where the stick, when tied on, should balance the rocket, so as to stand in an equilibrium on one's finger or the edge of a knife. The best wood for the sticks is dry deal, made thus. When you have cut and planed the sticks according to the dimensions given in the table, cut, on one of the flat sides at the top, a groove the length of the rocket, and as broad as the stick will allow; then, on the opposite flat side, cut two notches for the cord, which ties on the rocket, to lie in; one of these notches must be near the top of the stick, and

Of Moulds,
Cafes, Mix-
ture, Instru-
ments, &c.

Of Moulds,
Cases, Mix-
ture, Instru-
ments, &c.

and the other facing the neck of the rockets; the distance between these notches may easily be known, for the top of the stick should always touch the head of the rocket. When your rockets and sticks are ready, lay the rockets in the grooves in the sticks, and tie them on. Those who, merely for curiosity, may choose to make rockets of different sizes, from those expressed in the table of dimensions, may find the length of their sticks, by making them for rockets, from $\frac{1}{2}$ oz. to 1 lb. 60 diameters of the rocket long; and for rockets above 1 lb. 50 or 52 diameters will be a good length; their thickness at top may be about $\frac{1}{2}$ a diameter, and their breadth a very little more; their square at bottom is generally equal to $\frac{1}{2}$ the thickness at top. But although the dimensions of the sticks be very nicely observed, you must depend only on their balance; for, without a proper counterpoise, your rockets, instead of mounting perpendicularly, will take an oblique direction, and fall to the ground before they are burnt out.

51. *Boring Rockets which have been driven solid.*

FIG. 18. represents the plan of an apparatus, or lathe, for boring of rockets. A the large wheel, which turns the small one B, that works the rammer C: these rammers are of different sizes according to the rockets; they must be of the same diameter as the top of the bore intended, and continue that thickness a little longer than the depth of the bore required, and their points must be like that of an augre: the thick end of each rammer must be made square, and all of the same size, so as to fit into one socket, wherein they are fastened by a screw D. E the guide for the rammer, which is made to move backwards and forwards: so that, after you have marked the rammer $3\frac{1}{2}$ diameters of the rocket from the point, set the guide, allowing for the thickness of the fronts of the rocket boxes, and the neck and mouth of the rocket; so that when the front of the large box is close to the guide, the rammer may not go too far up the charge. F, boxes for holding the rockets, which are made so as to fit in one another; their sides must be equal in thickness to the difference of the diameters of the rockets, and their interior diameters equal to the exterior diameters of the rockets. To prevent the rockets turning round while boring, a piece of wood must be placed against the end of the box in the inside, and pressed against the tail of the rocket; this will also hinder the rammer from forcing the rocket backwards. G, a rocket in the box. H, a box that slides under the rocket-boxes to receive the borings for the rockets, which fall through holes made on purpose in the boxes; these holes must be just under the mouth of the rocket, one in each box, and all to correspond with each other.

Fig. 19. is a front view of the large rocket-box. I, an iron plate, in which are holes of different sizes, through which the rammer passes: this plate is fastened with a screw in the centre, so that when you change the rammer, you turn the plate round, but always let the hole you are going to use be at the bottom: the fronts of the other boxes must have holes in them to correspond with those in the plate. K, the lower part of the large box; which is made to fit the inside of the lathe, that all the boxes may move quite steady.

Fig. 20. is a perspective view of the lathe. L, the guide for the rammer, which is set by the screw at bottom.

Fig. 21. A view of the front of the guide facing the rammer. M, an iron plate, of the same dimensions as that on the front of the box, and placed in the same direction, and also to turn on a screw in the centre. N, the rocket-box which slides backwards and forwards: when you have fixed a rocket in the box, push it forwards against the rammer; and when you think the scoop of the rammer is full, draw the box back, and knock out the composition: this you must do till the rocket is bored, or it will be in danger of taking fire; and if you bore in a hurry, wet the end of the rammer now and then with oil to keep it cool.

Having bored a number of rockets, you must have taps of different sorts according to the rockets. These taps are a little longer than the bore: but when you use them, mark them $3\frac{1}{2}$ diameters from the point, allowing for the thickness of the rocket's neck; then, holding the rocket in one hand, you tap it with the other. One of these taps is represented by fig. 22. They are made in the same proportion as the fixed piercers, and are hollowed their whole length.

52. *Hand Machine used for boring of Rockets instead of a Lathe.*

These sort of machines answer very well, though not so expeditious as the lathes. But they are not so expensive to make, and they may be worked by one man; whereas the lathe will require three. Fig. 23. represents the machine. O, the rocket boxes, which are to be fixed, and not to slide as those in the lathe. PQ are guides for the rammers, that are made to slide together, as the rammer moves forward: the rammers for these sorts of machines must be made of a proper length, allowing for the thickness of the front of the boxes, and the length of the mouth and neck of the case; on the square end of these rammers must be a round shoulder of iron, to turn against the outside of the guide Q, by which means the guides are forced forwards. R, the stock which turns the rammer, and while turning must be pressed towards the rocket by the body of the man who works it; all the rammers are to be made to fit one stock.

To make large Gerbes.

Fig. 1. represents a wooden former; fig. 2. a gerbe complete, with its foot or stand. The cases for gerbes are made very strong, on account of the strength of the composition; which, when fired, comes out with great velocity: therefore, to prevent their bursting, the paper should be pasted, and the cases made as thick at the top as at the bottom. They should also have very long necks, for this reason; first, that the particles of iron will have more time to be heated, by meeting with greater resistance in getting out, than with a short neck, which would be burnt too wide before the charge be consumed; and spoil the effect: secondly, that with long necks the stars will be thrown to a great height, and will not fall before they are spent, or spread too much; but, when made to perfection, will rise and spread in such a manner as to form exactly a wheat-sheaf.

In the ramming of gerbes, there will be no need of a mould, the cases being sufficiently strong to support themselves,

Cases, Mix-
ture, Instru-
ments, &c.

Plate
ccccxix.

Of Moulds, themselves. But you are to be careful, before you begin to ram, to have a piece of wood made to fit in the neck; for if this be not done, the composition will fall into the neck, and leave a vacancy in the case, which will cause the case to burst so soon as the fire arrives at the vacancy. You must likewise observe, that the first ladle of charge, or second, if you think proper, be of some weak composition. When the case is filled, take out the piece of wood, and fill the neck with some slow charge. Gerbes are generally made about 6 diameters long, from the bottom to the top of the neck; their bore must be 1-5th narrower at top than at bottom. The neck is 1-6th diameter and $\frac{3}{4}$ long. T, a wooden foot or stand, on which the gerbe is fixed. This may be made with a choak or cylinder 4 or 5 inches long to fit the inside of the case, or with a hole in it to put in the gerbe; both these methods will answer the same. Gerbes produce a most brilliant fire, and are very beautiful when a number of them are fixed in the front of a building or a collection of fireworks.

N. B. Gerbes are made by their diameters, and their cases at bottom $\frac{1}{4}$ thick. The method of finding the interior diameter of a gerbe is thus: Supposing you would have the exterior diameter of the case, when made, to be 5 inches, then, by taking 2-4ths for the sides of the case, there will remain 2 $\frac{1}{2}$ inches for the bore, which will be a very good size. These sort of gerbes should be rammed very hard.

N. B. Gerbes are made by their diameters, and their cases at bottom $\frac{1}{4}$ thick.

The method of finding the interior diameter of a gerbe is thus: Supposing you would have the exterior diameter of the case, when made, to be 5 inches, then, by taking 2-4ths for the sides of the case, there will remain 2 $\frac{1}{2}$ inches for the bore, which will be a very good size. These sort of gerbes should be rammed very hard.

54. *Small Gerbes, or white Fountains,*

May be made of 4 oz. 8 oz. or 1 lb. cases, pasted and made very strong, of what length you please: but, before you fill them, drive in clay one diameter of their orifice high; and when you have filled a case, bore a vent through the centre of the clay to the composition: the common proportion will do for the vent, which must be primed with a slow charge. These sort of cases, without the clay, may be filled with Chinese fire.

55. *To make Pasteboard and Paper Mortars.*

Plate ccccxix. Fig. 3. represents a former, and fig. 4. an elm foot, for the mortar. Fig 5. represents a mortar complete: these mortars are best when made with pasteboard, well pasted before you begin; or instead of paste, you may use glue. For a cohorn mortar, which is 4 inches 2-5ths diameter, roll the pasteboard on the former 1-6th of its diameter thick; and, when dry, cut one end smooth and even; then nail and glue it on the upper part of the foot: when done, cut off the pasteboard at top, allowing for the length of the mortar 2 $\frac{1}{2}$ diameters from the mouth of the powder-chamber; then bind the mortar round with a strong cord wetted with glue. U, the bottom part of the foot 1 diameter 2-3ds broad, and 1 diameter high; and that part which goes into the mortar is 2-3ds of its diameter high. W, is a copper chamber for powder, made in a conical form; and is 1-3d of the diameter wide, 1 $\frac{1}{2}$ of its own diameter long. In the centre of the bottom of this chamber, make a small hole a little way down the foot; this hole must be met by another of the same size, made in the side of the foot, as is shown in the figure. If these holes are made true, and a copper pipe fitted into both, the mortar when loaded will prime itself; for the powder will naturally fall to the bottom of the first hole; then by putting a bit of

quick-match in the side hole, your mortar will be ready to be fired. Air-bal-loons, &c.

Mortars of 5 $\frac{1}{2}$, eight and ten inches diameter, may be made of paper or pasteboard, by the above method, and in the same proportion; but if larger, it will be best to have them made of brass. N. B. The copper chamber must have a small rim round its edge with holes in it, for screws to make it fast in the foot.

SECT. III. *To load Air-balloons, with the number of Stars, Serpents, Snakes, Rain-falls, &c. in Shells of each nature.*

56. *Mortars to throw Aigrettes, &c.*

WHEN you fill your shells, you must first put in the serpents, rains, stars, &c. or whatever they are composed of; then the blowing powder; but the shells must not be quite filled. All those things must be put in at the fuze hole; but marrons being too large to go in at the fuze hole, must be put in before the inside shell be joined. When the shells are loaded, glue and drive in the fuzes very tight. For a cohorn balloon, let the diameter of the fuze hole be $\frac{7}{8}$ ths of an inch; for a royal balloon, which is near 5 $\frac{1}{2}$ inches diameter, make the fuze hole 1 inch $\frac{1}{8}$ th diameter; for an 8-inch balloon, 1 inch $\frac{3}{8}$ ths; and for a 10-inch balloon, 1 inch $\frac{5}{8}$ ths.

Air-balloons are divided into 4 sorts; viz. first, illuminated balloons; second, balloons of serpents; third, balloons of reports, marrons, and crackers; and fourth, compound balloons. The number and quantities of each article for the different shells are as follow.

Coehorn balloon illuminated.

	oz.
Meal } powder {	1 $\frac{1}{2}$
Corn } powder {	0 $\frac{1}{2}$
Powder for the mortar	2

Length of the fuze composition, $\frac{3}{4}$ ths of an inch; 1 oz. drove or rolled stars, as many as will nearly fill the shell.

Coehorn balloon of serpents.

	oz.
Meal } powder {	1 $\frac{1}{4}$
Corn } powder {	1
Powder for the mortar	2 $\frac{1}{4}$

Length of the fuze composition $\frac{1}{2}$ ths of an inch: half-ounce cases drove 3 diameters, and bounced 3 diameters, and half-ounce cases drove 2 diameters and bounced 4, of each an equal quantity, and as many of them as will fit in easily placed head to tail.

Coehorn balloons of crackers and reports.

	oz.
Meal } powder {	1 $\frac{1}{4}$
Corn } powder {	0 $\frac{1}{2}$
Powder for the mortar	2

Length of the fuze composition $\frac{3}{4}$ ths of an inch. Reports 4, and crackers of 6 bounces as many as will fill the shell.

Compound coehorn balloons.

	oz. dr.
Meal } powder {	1 4
Corn } powder {	0 12
Powder for the mortar	2 4

Length of the fuze composition $\frac{1}{2}$ ths of an inch: $\frac{1}{2}$ ounce cases drove 3 $\frac{1}{2}$ diameters and bounced 2, 16; $\frac{3}{4}$ ounce cases drove 4 diameters and not bounced 10; blue string stars, 10; rolled stars, as many as will complete the balloon.

Air-bal-
loons, &c.

<i>Royal balloons illuminated.</i>		oz. dr.
Meal } powder {	1 8
Corn } powder {	0 12
Powder for the mortar		3 0

Length of the fuze composition $\frac{1}{2}$ ths of an inch ; 2 ounce strung stars, 34 ; rolled stars, as many as the shell will contain, allowing room for the fuze.

<i>Royal balloons of serpents.</i>		oz. dr.
Meal } powder {	1 0
Corn } powder {	1 8
Powder for the mortar		3 8

Length of the fuze composition 1 inch : 1 ounce-cases drove $3\frac{1}{2}$ and 4 diameters, and bounced 2, of each an equal quantity, sufficient to load the shell.

<i>Royal balloons with crackers and marrons.</i>		oz. dr.
Meal } powder {	1 8
Corn } powder {	1 4
Powder for firing the mortar		3 0

Length of the fuze composition $\frac{1}{4}$ ths of an inch ; reports 12, and completed with crackers of 8 bounces.

<i>Compound royal balloons.</i>		oz. dr.
Meal } powder {	1 5
Corn } powder {	1 6
Powder for the mortar		3 12

Length of the fuze composition 1 inch : $\frac{1}{2}$ ounce cases drove and bounced 2 diameters, 8 ; 2 ounce cases filled $\frac{3}{4}$ ths of an inch with star composition, and bounced 2 diameters, 8 ; silver rain-falls, 10 ; 2 ounce tailed stars, 16 ; rolled brilliant stars, 30. If this should not be sufficient to load the shell, you may complete it with gold rain-falls.

<i>Eight-inch balloons illuminated.</i>		oz. dr.
Meal } powder {	2 8
Corn } powder {	1 4
Powder for the mortar		9 0

Length of the fuze composition 1 inch $\frac{1}{2}$ th ; 2 ounce drove stars, 48 ; 2 ounce cases drove with star composition $\frac{3}{4}$ ths of an inch, and bounced 3 diameters, 12 ; and the balloon completed with 2 ounce drove brilliant stars.

<i>Eight-inch balloons of serpents.</i>		oz. dr.
Meal } powder {	2 0
Corn } powder {	2 0
Powder for the mortar		9 8

Length of the fuze composition 1 inch $\frac{3}{8}$ ths : 2 oz. cases drove $1\frac{1}{2}$ diameter and bounced 2, and 1 ounce cases drove 2 diameters and bounced $2\frac{1}{2}$, of each an equal quantity sufficient for the shell.

N. B. The star-composition drove in bounced cases must be managed thus : First, the cases must be pinched close at one end, then the corn-powder put in for a report, and the case pinched again close to the powder, only leaving a small vent for the star composition, which is drove at top, to communicate to the powder at the bounce-end.

<i>Compound eight-inch balloons.</i>		oz. dr.
Meal } powder {	2 8
Corn } powder {	1 12
Powder for the mortar		9 4

Length of the fuze composition $\frac{1}{8}$ th : 4 ounce cases drove with star composition $\frac{3}{4}$ ths of an inch, and bounced 3 diameters, 16 ; 2 ounce tailed stars, 16 ; 2 ounce drove brilliant stars, 12 ; silver rain-falls, 20 ; 1 ounce drove blue stars, 20 ; and 1 ounce cases drove and bounced 2 diameters, as many as will fill the shell.

Another of eight inches.

		oz. dr.	Air-bal- loons, &c.
Meal } powder {	2 8	
Corn } powder {	1 12	
Powder for the mortar		9 4	

Length of the fuze composition 1 inch $\frac{1}{2}$ th : crackers of 6 reports, 10 ; gold rains, 14 ; 2 ounce cases drove with star composition $\frac{3}{4}$ ths of an inch, and bounced 2 diameters, 16 ; 2 ounce tailed stars, 16 ; 2 ounce drove brilliant stars, 12 ; silver rains, 10 ; 1 ounce drove blue stars, 20 ; and 1 oz. cases drove with a brilliant charge 2 diameters and bounced 3, as many as the shell will hold.

<i>A compound ten-inch balloon.</i>		oz. dr.
Meal } powder {	3 4
Corn } powder {	2 8
Powder for the mortar		12 8

Length of the fuze composition $\frac{1}{2}$ ths of an inch : 1 ounce cases drove and bounced 3 diameters, 16. Crackers of 8 reports, 12 ; 4 ounce cases drove $\frac{1}{2}$ inch with star composition, and bounced 2 diameters, 14 ; 2 ounce cases drove with brilliant fire $1\frac{1}{4}$ diameter, and bounced 2 diameters, 16 : 2 ounce drove brilliant stars, 30 : 2 ounce drove blue stars, 3 ; gold rains, 20 ; silver rains, 20. After all these are put in, fill the remainder of the case with tailed and rolled stars.

<i>Ten-inch balloons of three charges.</i>		oz. dr.
Meal } powder {	3 0
Corn } powder {	3 2
Powder for the mortar		13 0

Length of the fuze composition 1 inch. The shell must be loaded with 2 ounce cases, drove with star composition $\frac{1}{4}$ th of an inch, and on that 1 diameter of gold fire, then bounced 3 diameters ; or with 2 ounce cases first filled 1 diameter with gold fire, then $\frac{1}{4}$ th of an inch with star composition, and on that $1\frac{1}{4}$ th diameter of brilliant fire. These cases must be well secured at top of the charge, lest they should take fire at both ends : but their necks must be larger than the common proportion.

57. To make Balloon Fuzes.

Fuzes for air-balloons are sometimes turned out of dry beech, with a cup at top to hold the quick-match, as you see in fig. 5. but if made with pasted paper, they will do as well : the diameter of the former for fuzes for coehorn balloons must be $\frac{1}{2}$ an inch ; for a royal fuze, $\frac{5}{8}$ ths of an inch ; for an 8-inch fuze, $\frac{3}{4}$ ths of an inch ; and for a 10-inch fuze, $\frac{7}{8}$ ths of an inch. Having rolled your cases, pinch and tie them almost close at one end ; then drive them down, and let them dry. Before you begin to fill them, mark on the outside of the case the length of the charge required, allowing for the thickness of the bottom ; and when you have rammed in the composition, take two pieces of quick-match about 6 inches long, and lay one end of each on the charge, and then a little meal powder, which ram down hard ; the loose ends of the match double up into the top of the fuze, and cover it with a paper cap to keep it dry. When you put the shells in the mortars, uncap the fuzes, and pull out the loose ends of the match, and let them hang on the sides of the balloons. The use of the match is, to receive the fire from the powder in the chamber of the mortar, in order to light the fuze : the shell being put in the mortar with the fuze uppermost, and exactly in the centre, sprinkle over it a little meal-powder, and it will be ready to be fired.

Fuzes

Air-bal-
loons, &c.

Fuzes made of wood must be longer than those of paper, and not bored quite through, but left solid about $\frac{1}{2}$ an inch at bottom; and when you use them, saw them off to a proper length, measuring the charge from the cup at top.

58. *Tourbillons.*

Having filled some cases within about $1\frac{1}{2}$ diameter, drive in a ladleful of clay; then pinch their ends close, and drive them down with a mallet. When done, find the centre of gravity of each case; where you nail and tie a stick, which should be $\frac{1}{2}$ an inch broad at the middle, and run a little narrower to the ends: these sticks must have their ends turned upwards, so that the cases may turn horizontally on their centres: at the opposite sides of the cases, at each end, bore a hole close to the clay with a gimblet, the size of the neck of a common case of the same nature; from these holes draw a line round the case, and at the under part of the case bore a hole with the same gimblet, within $\frac{1}{2}$ diameter of each line towards the centre; then from one hole to the other draw a right line. This line divide into three equal parts; and at X and Y (fig. 6.) bore a hole; then from these holes to the other two lead a quick-match, over which paste a thin paper. Fig. 7. represents a tourbillon as it should lie to be fired, with a leader from one side-hole A to the other B. When you fire tourbillons, lay them on a smooth table, with their sticks downwards, and burn the leader thro' the middle with a port-fire. They should spin three or four seconds on the table before they rise, which is about the time the composition will be burning from the side-holes to those at bottom.

To tourbillons may be fixed reports in this manner: In the centre of the case at top make a small hole, and in the middle of the report make another; then place them together, and tie on the report, and with a single paper secure it from fire: this done, your tourbillon is completed. By this method you may fix on tourbillons small cones of stars, rains, &c. but be careful not to load them too much. One-eighth of an inch will be enough for the thickness of the sticks, and their length equal to that of the cases.

59. *To make Mortars to throw Aigrettes, and to load and fire them.*

Mortars to throw aigrettes are generally made of pasteboard, of the same thickness as balloon mortars, and $2\frac{1}{2}$ diameters long in the inside from the top to the foot: the foot must be made of elm without a chamber, but flat at top, and in the same proportion as those for balloon mortars; these mortars must also be bound round with a cord as beforementioned: sometimes 8 or 9 of these mortars, of about three or four inches diameter, are bound all together, so as to appear but one: but when they are made for this purpose, the bottom of the foot must be of the same diameter as the mortars, and only $\frac{1}{2}$ diameter high. Your mortars being bound well together, fix them on a heavy solid block of wood. To load these mortars, first put on the inside bottom of each a piece of paper, and on it spread $1\frac{1}{2}$ oz. of meal and corn powder mixed; then tie your serpents up in parcels with quick-match, and put them in the mortar with their mouths downwards; but take care the parcels do not fit too tight in the mortars, and that all the serpents have been well primed with powder wetted with spirit of wine. On the top of the serpents in

Air bal-
loons, &c.

each mortar lay some paper or tow; then carry a leader from one mortar to the other all round, and then from all the outside mortars into that in the middle: these leaders must be put between the cases and the sides of the mortar, down to the powder at bottom: in the centre of the middle mortar fix a fire-pump, or brilliant fountain, which must be open at bottom, and long enough to project out of the mouth of the mortar; then paste paper on the tops of all the mortars.

Mortars thus prepared are called a *nest of serpents*, as represented by fig. 8. When you would fire these mortars, light the fire-pump C, which when consumed will communicate to all the mortars at once by means of the leaders. For mortars of 6, 8, or 10 inches diameter, the serpents should be made in 1 and 2 ounce cases 6 or 7 inches long, and fired by a leader brought out of the mouth of the mortar, and turned down the outside, and the end of it covered with paper, to prevent the sparks of the other works from setting it on fire. For a six-inch mortar, let the quantity of powder for firing be 2 oz.; for an 8-inch, $2\frac{1}{4}$ oz.; and for a 10-inch, $3\frac{1}{4}$ oz. Care must be taken in these, as well as small mortars, not to put the serpents in too tight, for fear of bursting the mortars. These mortars may be loaded with stars, crackers, &c.

If the mortars, when loaded, are sent to any distance, or liable to be much moved, the firing powder should be secured from getting amongst the serpents, which would endanger the mortars, as well as hurt their performance. To prevent which, load your mortars thus: First put in the firing powder, and spread it equally about; then cut a round piece of blue touch-paper, equal to the exterior diameter of the mortar, and draw on it a circle equal to the interior diameter of the mortar, and notch it all round as far as that circle; then paste that part which is notched, and put it down the mortar close to the powder, and stick the pasted edge to the mortar: this will keep the powder always smooth at bottom, so that it may be moved or carried anywhere without receiving damage. The large single mortars are called *pots des aigrettes*.

60. *Making, loading, and firing, of Pots des Brins.*

These are formed of pasteboard, and must be rolled pretty thick. They are usually made 3 or 4 inches diameter, and 4 diameters long; and pinched with a neck at one end, like common cases. A number of these are placed on a plank thus: Having fixed on a plank two rows of wooden pegs, cut in the bottom of the plank a groove the whole length under each row of pegs; then, through the centre of each peg, bore a hole down to the groove at bottom, and on every peg fix and glue a pot, whose mouth must fit tight on the peg: through all the holes run a quick-match, one end of which must go into the pot, and the other into the groove, which must have a match laid in it from end to end, and covered with paper, so that when lighted at one end it may discharge the whole almost instantaneously: in all the pots put about 1 oz. of meal and corn powder; then in some put stars, and others rains, snakes, serpents, crackers, &c. when they are all loaded, paste paper over their mouths. Two or three hundred of these pots being fired together make a very pretty show, by affording so great a variety of fires. Fig. 9. is a range of pots des brins, with a leader A, by which they are fired.

Air-bal-
loons. &c.61. *Pots des Saucissons,*

Are generally fired out of large mortars without chambers, the same as those for aigrettes, only somewhat stronger. Saucissons are made of 1 and 2 ounce cases, 5 or 6 inches long, and choaked in the same manner as serpents. Half the number which the mortar contains must be drove $1\frac{1}{2}$ diameter with composition, and the other half two diameters, so that when fired they may give two volleys of reports. But if the mortars are very strong, and will bear a sufficient charge to throw the saucissons very high, you may make three volleys of reports, by dividing the number of cases into three parts, and making a difference in the height of the charge. After they are filled, pinch and tie them at top of the charge almost close; only leaving a small vent to communicate the fire to the upper part of the case, which must be filled with corn-powder very near the top; then pinch the end quite close, and tie it: after this is done, bind the case very tight with waxed packthread, from the choak at top of the composition to the end of the case; this will make the case very strong in that part, and cause the report to be very loud. Saucissons should be rolled a little thicker of paper than the common proportion. When they are to be put in the mortar, they must be primed in their mouths, and fired by a case of brilliant fire fixed in their centre.

The charge for these mortars should be $\frac{1}{4}$ th or $\frac{1}{3}$ th more than for *pots des aigrettes* of the same diameter.

SECT. IV. *Different kinds of Rockets, with their Appendages and Combinations.*62. *To fix one Rocket on the top of another.*

WHEN sky-rockets are thus managed, they are called *towering rockets*, on account of their mounting so very high. Towering rockets are made after this manner: Fix on a pound-rocket a head without a collar: then take a four ounce rocket, which may be headed or bounced, and rub the mouth of it with meal-powder wetted with spirit of wine: when done, put it in the head of the large rocket with its mouth downwards; but before you put it in, stick a bit of quick-match in the hole of the clay of the pound-rocket, which match should be long enough to go a little way up the bore of the small rocket, to fire it when the large is burnt out, the 4 ounce rocket being too small to fill the head of the other, roll round it as much tow as will make it stand upright in the centre of the head: the rocket being thus fixed, paste a single paper round the opening of the top of the head of the large rocket. The large rocket must have only half a diameter of charge rammed above the piercer; for, if filled to the usual height, it would turn before the small one takes fire, and entirely destroy the intended effect: when one rocket is headed with another, there will be no occasion for any blowing powder; for the force with which it sets off will be sufficient to disengage it from the head of the first fired rocket. The sticks for these rockets must be a little longer than for those headed with stars, rains, &c.

63. *Caduceus Rocket,*

In rising, form two spiral lines, or double worm, by reason of their being placed obliquely, one opposite

the other; and their counterpoise in their centre, which causes them to rise in a vertical direction. Rockets for this purpose must have their ends choaked close, without either head or bounce, for a weight at top would be a great obstruction to their mounting; though I have known them sometimes to be bounced, but then they did not rise so high as those that were not; nor do any caduceus rockets ascend so high as single, because of their serpentine motion, and likewise the resistance of air, which is much greater than two rockets of the same size would meet with if fired singly.

By 2d fig. 9. you see the method of fixing these rockets: the sticks for this purpose must have all their sides alike, which sides should be equal to the breadth of a stick proper for a sky-rocket of the same weight as those you intend to use, and to taper downwards as usual, long enough to balance them, one length of a rocket from the cross stick; which must be placed from the large stick 6 diameters of one of the rockets, and its length 7 diameters; so that each rocket, when tied on, may form with the large stick an angle of 60 degrees. In tying on the rockets, place their heads on the opposite sides of the cross stick, and their ends on the opposite sides of the long stick; then carry a leader from the mouth of one into that of the other. When these rockets are to be fired, suspend them between two hooks or nails, then burn the leader through the middle, and both will take fire at the same time. Rockets of 1 lb. are a good size for this use.

64. *Honorary Rockets,*

Are the same as sky-rockets, except that they carry no head nor report, but are closed at top, on which is fixed a cone; then on the case, close to the top of the stick, you tie on a 2 ounce case, about 5 or 6 inches long, filled with a strong charge, and pinched close at both ends; then in the reverse sides, at each end, bore a hole in the same manner as in tourbillons; from each hole carry a leader into the top of the rocket. When the rocket is fired, and arrived to its proper height, it will give fire to the case at top; which will cause both rocket and stick to spin very fast in their return, and represent a worm of fire descending to the ground.

There is another method of placing the small case, which is by letting the stick rise a little above the top of the rocket, and tying the case to it, so as to rest on the rocket: these rockets have no cones.

There is also a third method by which they are managed, which is thus: In the top of a rocket fix a piece of wood, in which drive a small iron spindle; then make a hole in the middle of the small case, through which put the spindle: then fix on the top of it a nut, to keep the case from falling off; when this is done, the case will turn very fast, without the rocket: but this method does not answer so well as either of the former.

Fig. 10. is the honorary rocket complete. The best sized rockets for this purpose are those of 1 lb.

65. *To divide the tail of a Sky-rocket so as to form an Arch when ascending.*

Having some rockets made, and headed according to fancy, and tied on their sticks; get some sheet tin, and cut it into round pieces about 3 or 4 inches diameter; then on the stick of each rocket, under the mouth of the case, fix one of these pieces of tin 16 inches from the rocket's neck, and support it by a wooden bracket,

as

Rockets,
&c.

as strong as possible: the use of this is, that when the rocket is ascending the fire will play with great force on the tin, which will divide the tail in such a manner that it will form an arch as it mounts, and will have a very good effect when well managed: if there is a short piece of port-fire, of a strong charge, tied to the end of the stick, it will make a great addition; but this must be lighted before you fire the rocket.

66. *To make several Sky-rockets rise in the same direction, and equally distant from each other.*

Take six, or any number of sky-rockets, of what size you please, then cut some strong packthread into pieces of 3 or 4 yards long, and tie each end of these pieces to a rocket in this manner: Having tied one end of your packthread round the body of one rocket, and the other end to another, take a second piece of packthread and make one end of it fast to one of the rockets already tied, and the other end to a third rocket, so that all the rockets, except the two outside, will be fastened to two pieces of packthread: the length of thread from one rocket to the other may be what the maker pleases; but the rockets must be all of a size, and their heads filled with the same weight of stars, rains, &c.

Having thus done, fix in the mouth of each rocket a leader of the same length; and when you are going to fire them, hang them almost close; then tie the ends of the leaders together, and prime them: this prime being fired, all the rockets will mount at the same time, and divide as far as the strings will allow; which division they will keep, provided they are all rammed alike, and well made. They are called by some *chained rockets*.

67. *Signal Sky-rockets*

Are made of several kinds, according to the different signals intended to be given; but in artificial fireworks, two sorts are only used, which are one with reports and the other without; but those for the use of the navy and army are headed with stars, serpents, &c.—Rockets which are to be bounced must have their cases made $1\frac{1}{2}$ or 2 diameters longer than the common proportion; and after they are filled, drive in a double quantity of clay, then bounce and pinch them after the usual manner, and fix on each a cap.

Signal sky-rockets without bounces, are only sky-rockets closed and capped: these are very light, therefore do not require such heavy sticks as those with loaded heads; for which reason you may cut one length of the rocket off the stick, or else make them thinner.

Signal rockets with reports are fired in small flights; and often both these, and those without reports, are used for a signal to begin firing a collection of works.

68. *To fix a Sky-rocket with its Stick on the top of another.*

Rockets thus managed make a pretty appearance, by reason of a fresh tail being seen when the second rocket takes fire, which will mount to a great height. The method of preparing these rockets is thus: Having filled a two-pounder, which must be filled only half a diameter above the piercer, and its head not more than 10 or 12 stars; the stick of this rocket, must be made a little thicker than common; and when made, cut it in half the flat way, and in each half make a groove, so that when the two halves are joined, the hollow made by the grooves may be large enough to hold the stick

of a half-pound rocket; which rocket make and head as usual: put the stick of this rocket into the hollow of the large one, so far that the mouth of the rocket may rest on the head of the two-pounder; from whose lead carry a leader into the mouth of the small rocket; which being done, your rockets will be ready for firing.

2d 68. *To fix two or more Sky-rockets on one Stick.*

Two, three, or six sky-rockets, fixed on one stick, and fired together, make a grand and beautiful appearance; for the tails of all will seem but as one of an immense size, and the breaking of so many heads at once will resemble the bursting of an air-balloon. The management of this device requires a skilful hand; but if the following instructions be well observed, even by those who have not made a great progress in this art, there will be no doubt of the rockets having the desired effect.

Rockets for this purpose must be made with the greatest exactness, all rammed by the same hand, in the same mould, and out of the same proportion of composition; and after they are filled and headed, must all be of the same weight. The stick must also be well made (and proportioned) to the following directions: first, supposing your rockets to be $\frac{1}{2}$ pounders, whose sticks are 6 feet 6 inches long, then if 2, 3, or 6 of these are to be fixed on 1 stick, let the length of it be 9 feet 9 inches; then cut the top of it into as many sides as there are rockets, and let the length of each side be equal to the length of 1 of the rockets without its head, and in each side cut a groove (as usual); then from the grooves plane it round, down to the bottom, where its thickness must be equal to half the top of the round part. As their thickness cannot be exactly ascertained, we shall give a rule which generally answers for any number of rockets above two: the rule is this; that the stick at top must be thick enough, when the grooves are cut, for all the rockets to lie, without pressing each other, though as near as possible.

When only 2 rockets are to be fixed on one stick, let the length of the stick be the last given proportion, but shaped after the common method, and the breadth and thickness double the usual dimensions. The point of poise must be in the usual place (let the number of rockets be what they will): if sticks made by the above directions should be too heavy, plane them thinner; and if too light, make them thicker; but always make them of the same length.

When more than two rockets are tied on one stick, there will be some danger of their flying up without the stick, unless the following precaution is taken: For cases being placed on all sides, there can be no notches for the cord which ties on the rockets to lie in; therefore, instead of notches, drive a small nail in each side of the stick; between the necks of the cases: and let the cord, which goes round their necks, be brought close under the nails; by this means the rockets will be as secure as when tied on singly. Your rockets being thus fixed, carry a quick-match, without a pipe, from the mouth of one rocket to the other; this match being lighted will give fire to all at once.

Though the directions already given may be sufficient for these rockets, we shall here add an improvement on a very essential part of this device, which is, that of hanging the rockets to be fired; for before the following

Rockets.
&c.

following method was hit upon, many essays proved unsuccessful. Instead, therefore, of the old and common manner of hanging them on nails or hooks, make use of this contrivance: Have a ring made of strong iron wire, large enough for the stick to go in as far as the mouths of the rockets; then let this ring be supported by a small iron, at some distance from the post or stand to which it is fixed; then have another ring, fit to receive and guide the small end of the stick. Rockets thus suspended will have nothing to obstruct their fire; but when they are hung on nails or hooks, in such a manner that some of their mouths are against or upon a rail, there can be no certainty of their rising in a vertical direction.

69. *To fire Sky-rockets without Sticks.*

You must have a stand, of a block of wood, a foot diameter, and make the bottom flat, so that it may stand steady: in the centre of the top of this block draw a circle $2\frac{1}{2}$ inches diameter, and divide the circumference of it into three equal parts; then take 3 pieces of thick iron wire, each about three feet long, and drive them into the block, 1 at each point made on the circle; when these wires are drove in deep enough to hold them fast and upright, so that the distance from one to the other is the same at top as at bottom, the stand is complete.

The stand being thus made, prepare your rockets thus: Take some common sky-rockets, of any size, and head them as you please; then get some balls of lead, and tie to each a small wire 2 or $2\frac{1}{2}$ feet long, and the other end of each wire to tie to the neck of a rocket. These balls answer the purpose of sticks when made of a proper weight, which is about 2-3ds the weight of the rocket; but when they are of a proper size, they will balance the rocket in the same manner as a stick, at the usual point of poise. To fire these, hang them, one at a time, between the tops of the wires, letting their heads rest on the point of the wires, and the balls hang down between them: if the wires should be too wide for the rockets, press them together till they fit; and if too close, force them open; the wires for this purpose must be softened, so as not to have any spring, or they will not keep their position when pressed close or opened.

70. *Rain-falls and Stars for Sky-rockets, Double and Single.*

Gold and silver rain compositions are drove in cases that are pinched quite close at one end: if you roll them dry, 4 or 5 rounds of paper will be strong enough; but if they are pasted, 3 rounds will do; and the thin sort of cartridge-paper is best for those small cases, which in rolling you must not turn down the inside edge as in other cases, for a double edge would be too thick for so small a bore. The moulds for rain-falls should be made of brass, and turned very smooth in the inside; or the cases, which are so very thin, would tear in coming out; for the charge must be drove in tight; and the better the case fits the mould, the more driving it will bear. These moulds have no nipple, but instead thereof they are made flat. As it would be very tedious and troublesome to shake the composition out of such small ladles as are used for these cases, it will be necessary to have a funnel made of thin tin, to fit on the top of the case, by the help of which you may fill them very fast. For single rain-

falls for 4 oz. rockets, let the diameter of the former be $\frac{2-16}{16}$ ths of an inch, and the length of the case 2 inches; for 8 oz. rockets, $\frac{4-16}{16}$ ths and 2 diameters of the rocket long; for 1 lb. rockets, $\frac{5-16}{16}$ ths, and 2 diameters of the rocket long; for 2 lb. rockets, $\frac{5-16}{16}$ ths, and $3\frac{1}{2}$ inches long; for 4 lb. rockets, $\frac{6-16}{16}$ ths, and $4\frac{1}{2}$ inches long; and for 6-pounders, $\frac{7-16}{16}$ ths diameter, and 5 inches long.

Of double rain-falls there are two sorts. For example, some appear first like a star, and then as rain; and some appear first as rain, and then like a star. When you would have stars first, you must fill the cases, within $\frac{1}{2}$ inch of the top, with rain-composition, and the remainder, with star-composition; but when you intend the rain should be first, drive the case $\frac{1}{2}$ an inch with star-composition, and the rest with rain. By this method may be made many changes of fire; for in large rockets you may make them first burn as stars, then rain, and again as stars; or they may first show rain, then stars, and finish with a report; but when they are thus managed, cut open the first rained end, after they are filled and bounced, at which place prime them. The star-composition for this purpose must be a little stronger than for rolled stars.

Strung-stars. First take some thin paper, and cut it into pieces of $1\frac{1}{2}$ inch square, or thereabouts; then on each piece lay as much dry star-composition as you think the paper will easily contain; then twist up the paper as tight as you can; when done, rub some paste on your hands, and roll the stars between them; then set them to dry: your stars being thus made, get some flax or fine tow, and roll a little of it over each star; then paste your hands and roll the stars as before, and set them again to dry; when they are quite dry, with a piercer make a hole through the middle of each, into which run a cotton quick-match, long-enough to hold 10 or 12 stars at 3 or 4 inches distance: but any number of stars may be strung together by joining the match.

Tailed stars. These are called *tailed stars*, because there are a great number of sparks issuing from them, which represent a tail like that of a comet. Of these there are two sorts; which are *rolled*, and *drove*: when rolled, they must be moistened with a liquor made of half a pint of spirit of wine and half a gill of thin size, of this as much as will wet the composition enough to make it roll easy; when they are rolled, sift meal-powder over them, and set them to dry.

When tailed stars are drove, the composition must be moistened with spirit of wine only, and not made so wet as for rolling: 1 and 2 oz. cases, rolled dry, are best for this purpose; and when they are filled, unroll the case within 3 or 4 rounds of the charge, and all that you unroll cut off; then paste down the loose edge: 2 or 3 days after the cases are filled, cut them in pieces 5 or 6-8ths of an inch in length: then melt some wax, and dip one end of each piece into it, so as to cover the composition: the other end must be rubbed with meal-powder wetted with spirit of wine.

Drove stars. Cases for drove stars are rolled with paste, but are made very thin of paper. Before you begin to fill them, damp the composition with spirit of wine that has had some camphor dissolved in it: you may ram them indifferently hard, so that you do not break or sack the case; to prevent which, they should

Rockets,
&c.

Rockets,
&c.

should fit tight in the mould. They are drove in cafes of several sizes, from 8 drams to 4 oz. When they are filled in $\frac{1}{2}$ oz. cafes, cut them in pieces of $\frac{1}{2}$ of an inch long; if 1 oz. cafes, cut them in pieces of 1 inch; if 2 oz. cafes, cut them in pieces of $1\frac{1}{2}$ inch long; and if 4 oz. cafes, cut them in pieces of $1\frac{1}{2}$ inch long: having cut your stars of a proper size, prime both ends with wet meal-powder. These stars are seldom put in rockets, they being chiefly intended for air-balloons, and drove in cafes, to prevent the composition from being broken by the force of the blowing powder in the shell.

Rolling stars are commonly made about the size of a musket-ball; though they are rolled of several sizes, from the bigness of a pistol-ball to 1 inch diameter; and sometimes very small, but are then called *sparks*. Great care must be taken in making stars, first, that the several ingredients are reduced to a fine powder; secondly, that the composition is well worked and mixed. Before you begin to roll, take about a pound of composition, and wet it with the following liquid, enough to make it stick together and roll easy: Spirit of wine 1 quart, in which dissolve $\frac{1}{4}$ of an ounce of isinglass. If a great quantity of composition be wetted at once, the spirit will evaporate, and leave it dry, before you can roll it into stars: having rolled up one proportion, shake the stars in meal-powder, and set them to dry, which they will do in 3 or 4 days; but if you should want them for immediate use, dry them in an earthen pan over a slow heat, or in an oven. It is very difficult to make the stars all of an equal size when the composition is taken up promiscuously with the fingers; but by the following method they may be made very exact: When the mixture is moistened properly, roll it on a flat smooth stone, and cut it into square pieces, making each square large enough for the stars you intend. There is another method used by some to make stars, which is by rolling the composition in long pieces, and then cutting off the star, so that each star will be of a cylindrical form: but this method is not so good as the former; for, to make the composition roll this way, it must be made very wet, which makes the stars heavy, as well as weakens them. All stars must be kept as much from air as possible, otherwise they will grow weak and bad.

71. *Scrolls for Sky-rockets.*

Cafes for scrolls should be made 4 or 5 inches in length, and their interior diameter $\frac{3}{8}$ ths of an inch: one end of these cafes must be pinched quite close, before you begin to fill; and when filled, close the other end: then in the opposite sides make a small hole at each end, to the composition, in the same manner as in tourbillons; and prime them with wet meal-powder. You may put in the head of a rocket as many of these cafes as it will contain: being fired they turn very quick in the air, and form a scroll or spiral line. They are generally filled with a strong charge, as that of serpents or brilliant fire.

72. *Swarmers, or small Rockets.*

Rockets that go under the denomination of *swarmers*, are those from 2. oz. downwards. These rockets are fired sometimes in flights, and in large water-works, &c. Swarmers of 1 and 2 oz. are bored, and made in the same manner as large rockets, except that,

when headed, their heads must be put on without a collar: the number of strokes for driving 1 oz. must be 8, and for 2 oz. 12.

All rockets under 1 oz. are not bored, but must be filled to the usual height with composition, which generally consists of fine meal-powder 4 oz. and charcoal or steel-dust 2 drams: the number of strokes for ramming these small swarmers is not material, provided they are rammed true, and moderately hard. The necks of unbored rockets must be in the same proportion as in common cafes.

73. *Stands for Sky-rockets.*

Care must be taken, in placing the rockets when they are to be fired, to give them a vertical direction at their first setting out; which may be managed thus. Have two rails of wood, of any length, supported at each end by a perpendicular leg, so that the rails be horizontal, and let the distance from one to the other be almost equal to the length of the sticks of the rockets intended to be fired; then in the front of the top rail drive square hooks at 8 inches distance, with their points turning sidewise, so that when the rockets are hung on them, the points will be before the sticks and keep them from falling or being blown off by the wind: in the front of the rail at bottom must be staples, drove perpendicular under the hooks at top; through these staples put the small ends of the rocket-sticks. Rockets are fired by applying a lighted port-fire to their mouths.

N. B. When sky-rockets are made to perfection, and fired, they will stand 2 or 3 seconds on the hook before they rise, and then mount up briskly, with a steady motion, carrying a large tail from the ground all the way up, and just as they turn break and disperse the stars.

74. *Girandole Chests for Flights of Rockets.*

These are generally composed of four sides, of equal dimensions; but may be made of any diameter, according to the number of rockets designed to be fired; its height must be in proportion to the rockets, but must always be a little higher than the rockets with their sticks. When the sides are joined, fix in the top, as far down the chest as the length of one of the rockets with its cap on. In this top, make as many square or round holes to receive the rocket-sticks, as you intend to have rockets; but let the distance between them be sufficient for the rockets to stand without touching one another; then from one hole to another cut a groove large enough for a quick-match to lie in: the top being thus fixed, put in the bottom, at about 14 foot distance from the bottom of the chest; in this bottom must be as many holes as in the top, and all to correspond; but these holes need not be so large as those in the top.

To prepare your chest, you must lay a quick-match, in all the grooves, from hole to hole; then take some sky-rockets, and rub them in the mouth with wet meal-powder, and put a bit of match up the cavity of each; which match must be long enough to hang a little below the mouth of the rocket. Your rockets and chest being prepared according to the above directions, put the sticks of the rockets through the holes in the top and bottom of the chest, so that their mouths may rest on the quick-match in the grooves: by which all the rockets will be fired at once; for by giving fire to any part

Rockets,
&c.

part of the match, it will communicate to all the rockets in an instant. As it would be rather troublesome to direct the sticks from the top to the proper holes in the bottom, it will be necessary to have a small door in one of the sides, which, when opened, you may see how to place the sticks. Flights of rockets being seldom set off at the beginning of any fire-works, they are in danger of being fired by the sparks from wheels, &c. therefore, to preserve them, a cover should be made to fit on the chest, and the door in the side kept shut.

75. *Serpents or Snakes for Pots of Aigrettes, small Mortars, Sky-rockets, &c.*

Serpents for this use are made from $2\frac{1}{2}$ inches to 7 inches long, and their formers from $3\text{-}16$ ths to $5\text{-}8$ ths of an inch diameter; but the diameter of the cafes must always be equal to 2 diameters of the former. They are rolled and choaked like other cafes, and filled with composition from $5\text{-}8$ ths of an inch to $1\frac{1}{2}$ inch high, according to the size of the mortars or rockets they are designed for; and the remainder of the cafes bounced with corn-powder, and afterwards their ends pinched and tied close: before they are used, their mouths must be primed with wet meal-powder.

76. *Leaders, or Pipes of Communication.*

The best paper for leaders is elephant; which you cut into long slips 2 or 3 inches broad, so that they may go 3 or 4 times round the former, but not more: when they are very thick, they are too strong for the paper which fastens them to the works, and will sometimes fly off without leading the fire. The formers for these leaders are made from 2 to $6\text{-}16$ ths of an inch diameter; but $4\text{-}16$ ths is the size generally made use of. The formers are made of smooth brass wire: when you use them, rub them over with grease, or keep them wet with paste, to prevent their sticking to the paper, which must be pasted all over. In rolling of pipes, make use of a rolling-board, but use it lightly: having rolled a pipe, draw out the former with one hand, holding the pipe as light as possible with the other; for if it press against the former, it will stick and tear the paper.

N. B. Make your leaders of different lengths, or in clothing of works you will cut a great many to waste. Leaders for marron batteries must be made of strong cartridge paper.

77. *Crackers.*

Cut some cartridge paper into pieces $3\frac{1}{2}$ inches broad, and one foot long; one edge of each fold down lengthwise about $\frac{3}{4}$ of an inch broad; then fold the double edge down $\frac{1}{4}$ of an inch, and turn the single edge back half over the double fold; then open it, and lay all along the channel, which is formed by the folding of the paper, some meal-powder; then fold it over and over till all the paper is doubled up, rubbing it down every turn; this done, bend it backwards and forwards, $2\frac{1}{2}$ inches, or thereabouts, at a time, as oft as the paper will allow; then hold all these folds flat and close, and with a small pinching cord give one turn round the middle of the cracker, and pinch it close; then bind it with a packthread as tight as you can; then, in the place where it was pinched, prime one end of it, and cap it with touch-paper. When these crackers are fired, they will give a report at every turn of the paper: if you would have a great number of bounces,

you must cut the paper longer, or join them after they are made; but if they are made very long before they are pinched, you must have a piece of wood with a groove in it, deep enough to let in half the cracker; this will hold it straight while it is pinching. Fig. 12. represents a cracker complete.

78. *Single Reports.*

Cafes for reports are generally rolled on one and two oz. formers, and seldom made larger but on particular occasions; they are made from two to four inches long, and very thick of paper. Having rolled a cafe, pinch one end quite close, and drive it down: then fill the cafe with corn-powder, only leaving room to pinch it at top; but before you pinch it, put in a piece of paper at top of the powder. Reports are fired by a vent, bored in the middle, or at one end, just as required.

79. *Marrons.*

Formers for marrons are from $\frac{3}{4}$ of an inch to $1\frac{1}{2}$ diameter. Cut the paper for the cafes twice the diameter of the former broad, and long enough to go three times round: when you have rolled a cafe, paste down the edge and tie one end close; then with the former drive it down to take away the wrinkles, and make it flat at bottom; then fill the cafe with corn-powder one diameter and $\frac{1}{4}$ high, and fold down the rest of the cafe tight on the powder. The marron being thus made, wax some strong pack-thread, with shoemakers wax; this thread wind up in a ball, then unwind two or three yards of it, and that part which is near the ball make fast to a hook; then take a marron, and stand as far from the hook as the pack-thread will reach, and wind it lengthwise round the marron as close as you can, till it will hold no more that way; then turn it, and wind the packthread on the short way, then lengthwise again, and so on till the paper is all covered; then make fast the end of the packthread, and beat down both ends of the marron to bring it in shape. The method of firing marrons is by making a hole at one end with an awl, and putting in a piece of quick match; then take a piece of strong paper, in which wrap up the marron with two leaders, which must be put down to the vent, and the paper tied tight round them with small twine: these leaders are bent on each side, and their loose ends tied to other marrons, and are nailed in the middle to the rail of the stand, as in fig. 13. The use of winding the packthread in a ball is, that you may let it out as you want it, according to the quantity the marron may require; and that it may not be tied in knots, which would spoil the marron.

80. *Marron Batteries,*

If well managed, will keep time to a march, or a slow piece of music. Marron batteries are made of several stands, with a number of cross rails for the marrons; which are regulated by leaders, by cutting them of different lengths, and nailing them tight, or loose, according to the time of the music. In marron batteries you must use the large and small marrons, and the nails for the pipes must have flat heads.

81. *Line Rockets.*

Are made and drove as the sky-rockets, but have no heads, and the cafes must be cut close to the clay: they are sometimes made with six or seven changes, but in general not more than four or five. The method of managing those rockets is thus: First, have a piece of light wood, the length of one of the rockets, turned round

Rockets, &c. round about $2\frac{1}{2}$ inches diameter, with a hole through the middle lengthwise, large enough for the line to go easily through: if you design four changes, have four grooves cut in the swivel, one opposite the other, to lay the rockets in.

The mouths of the rockets being rubbed with wet meal-powder, lay them in the grooves head to tail, and tie them fast; from the tail of the first rocket carry a leader to the mouth of the second, and from the second to the third, and so on to as many as there are on the swivel, making every leader very secure; but in fixing these pipes, take care that the quick-match does not enter the bores of the rockets: the rockets being fixed on the swivel and ready to be fired, have a line 100 yards long, stretched and fixed up tight, at any height from the ground; but be sure to place it horizontally: this length of line will do for $\frac{1}{4}$ lb. rockets; but if larger, the line must be longer. Before you put up the line, put one end of it through the swivel; and when you fire the line rocket, let the mouth of that rocket which you fire first face that end of the line where you stand; then the first rocket will carry the rest to the other end of the line, and the second will bring them back; and so they will run out and in according to the number of rockets: at each end of the line there must be a piece of flat wood for the rocket to strike against, or its force will cut the line. Let the line be well soaped, and the hole in the swivel very smooth.

82. Different Decorations for Line Rockets.

To line rockets may be fixed great variety of figures, such as flying dragons, Mercuries, ships, &c. Or they may be made to run on the line like a wheel; which is done in this manner. Have a flat swivel made very exact, and on it tie two rockets obliquely, one on each side, which will make it turn round all the way it goes, and form a circle of fire; the charge for these rockets should be a little weaker than common. If you would show two dragons fighting, get two swivels made square, and on each tie three rockets together on the under side; then have two flying dragons made of tin, and fix one of them on the top of each swivel, so as to stand upright; in the mouth of each dragon put a small case of common fire, and another at the end of the tail; you may put two or three port-fires, of a strong charge, on one side of their bodies, to show them. This done, put them on the line, one at each end; but let there be a swivel in the middle of the line to keep the dragons from striking together: before you fire the rockets, light the cases on the dragons; and if care be taken in firing both at the same time, they will meet in the middle of the line, and seem to fight. Then they will run back and return with great violence; which will have a very pleasing effect. The line for these rockets must be very long, or they will strike too hard together.

82. Chinese Flyers.

Cases for flyers may be made of different sizes, from one to eight ounces: they must be made thick of paper, and eight interior diameters long; they are rolled in the same manner as tourbillons, with a straight pasted edge, and pinched close at one end. The method of filling them is, the case being put in a mould, whose cylinder, or foot, must be flat at top without a nipple, fill it within $\frac{1}{4}$ a diameter of the middle; then ram in $\frac{1}{2}$ a diameter of clay, on that as much composition as

VOL. XV.

before, on which drive $\frac{1}{4}$ a diameter of clay; then pinch the case close, and drive it down flat; after this is done, bore a hole exactly through the centre of the clay in the middle; then in the opposite sides, at both ends, make a vent; and in that side you intend to fire first make a small hole to the composition near the clay in the middle, from which carry a quick match, covered with a single paper, to the vent at the other end; then, when the charge is burnt on one side, it will, by means of the quick-match, communicate to the charge on the other (which may be of a different sort). The flyers being thus made, put an iron pin, that must be fixed in the work on which they are to be fired, and on which they are to run, through the hole in the middle; on the end of this pin must be a nut to keep the flyer from running off. If you would have them turn back again after they are burnt, make both the vents at the ends on the same side, which will alter its course the contrary way.

84. Table Rockets,

Are designed merely to show the truth of driving, and the judgment of a fire-worker, they having no other effect, when fired, than spinning round in the same place where they begin, till they are burnt out, and showing nothing more than an horizontal circle of fire.

The method of making these rockets is—Have a cone turned out of hard wood $2\frac{1}{2}$ inches diameter, and as much high; round the base of it draw a line; on this line fix four spokes, two inches long each, so as to stand one opposite the other; then fill four nine-inch one lb. cases with any strong composition, within two inches of the top: these cases are made like tourbillons, and must be rammed with the greatest exactness.

Your rockets being filled, fix their open ends on the short spoke; then in the side of each case bore a hole near the clay; all these holes, or vents, must be so made that the fire of each case may act the same way; from these vents carry leaders to the top of the cone, and tie them together. When you would fire the rockets, set them on a smooth table, and light the leaders in the middle, and all the cases will fire together (see fig. 14.) and spin on the point of the cone.

These rockets may be made to rise like tourbillons, by making the cases shorter, and boring four holes in the under side of each at equal distances: this being done, they are called *double tourbillons*.

Note. All the vents in the under side of the cases must be lighted at once; and the sharp point of the cone cut off, at which place make it spherical.

SECT. V. Of Wheels and other Works.

85. Single Vertical Wheels.

THERE are different sorts of vertical wheels; some having their fells of a circular form, others of an hexagon, octagon, or decagon form, or any number of sides, according to the length of the cases you design for the wheel: your spokes being fixed in the nave, nail slips of tin, with their edges turned up, so as to form grooves for the cases to lie in, from the end of one spoke to another; then tie your cases in the grooves head to tail, in the same manner as those on the horizontal water-wheel, so that the cases successively taking fire from one another, will keep the wheel in an equal rotation. Two of these wheels are very oft fired together, one on each

4 U

side

Plate
ccccxxix.

Of Wheels, &c. side of a building; and both lighted at the same time, and all the cafes filled alike, to make them keep time together; which they will do if made by the following directions. In all the cafes of both wheels, except the first, on each wheel drive two or three ladles full of slow fire, in any part of the cafes; but be careful to ram the same quantity in each cafe, and in the end of one of the cafes, on each wheel, you may ram one ladlefull of dead-fire composition, which must be very lightly drove; you may also make many changes of fire by this method.

Let the hole in the nave of the wheel be lined with brais, and made to turn on a smooth iron spindle. On the end of this spindle let there be a nut, to screw off and on; when you have put the wheel on the spindle, screw on the nut, which will keep the wheel from flying off. Let the mouth of the first cafe be a little raised. See fig. 15. Vertical wheels are made from 10 inches to 3 feet diameter, and the size of the cafes must differ accordingly; 4-oz. cafes will do for wheels of 14 or 16 inches diameter, which is the proportion generally used. The best wood for wheels of all sorts is a light and dry beech.

86. Horizontal Wheels,

Are best when their fells are made circular; in the middle of the top of the nave must be a pintle, turned out of the same piece as the nave, two inches long, and equal in diameter to the bore of one of the cafes of the wheel: there must be a hole bored up the centre of the nave, within half an inch of the top of the pintle. The wheel being made, nail at the end of each spoke (of which there should be six or eight) a piece of wood, with a groove cut in it to receive the cafe. Fix these pieces in such a manner that half the cafes may incline upwards and half downwards, and that, when they are tied on, their heads and tails may come very near together; from the tail of one cafe to the mouth of the other carry a leader, which secure with pasted paper. Besides these pipes, it will be necessary to put a little meal-powder inside the pasted paper, to blow off the pipe, that there may be no obstruction to the fire from the cafes. By means of these pipes the cafe will successively take fire, burning one upwards and the other downwards. On the pintle fix a cafe of the same sort as those on the wheel; this cafe must be fired by a leader from the mouth of the last cafe on the wheel, which cafe must play downwards: instead of a common cafe in the middle, you may put a cafe of Chinese fire, long enough to burn as long as two or three of the cafes on the wheel.

Horizontal wheels are oft fired two at a time, and made to keep time like vertical wheels, only they are made without any slow or dead fire; 10 or 12 inches will be enough for the diameter of wheels with six spokes. Fig. 16. represents a wheel on fire, with the first cafe burning.

87. Spiral Wheels,

Are only double horizontal wheels, and made thus: The nave must be about 6 inches long, and somewhat thicker than the single sort; instead of the pintle at top, make a hole for the cafe to be fixed in, and two sets of spokes, one set near the top of the nave, and the other near the bottom. At the end of each spoke cut a groove wherein you tie the cafes, there being no fell; the spokes should not be more than $3\frac{1}{2}$ inches long from

the nave, so that the wheel may not be more than 8 or 9 inches diameter; the cafes are placed in such a manner, that those at top play down, and those at bottom play up, but let the third or fourth cafe play horizontally. The cafe in the middle may begin with any of the others you please: 6 spokes will be enough for each set, so that the wheel may consist of 12 cafes, besides that on the top: the cafes 6 inches each.

88. Plural Wheels,

Are made to turn horizontally, and to consist of three sets of spokes, placed 6 at top, 6 at bottom, and 4 in the middle, which must be a little shorter than the rest: let the diameter of the wheel be 10 inches; the cafes must be tied on the ends of the spokes in grooves cut on purpose, or in pieces of wood nailed on the ends of the spokes, with grooves cut in them as usual: in clothing these wheels, make the upper set of cafes play obliquely downwards, the bottom set obliquely upwards, and the middle set horizontally. In placing the leaders, you must order it so that the cafes may burn thus, viz. first up, then down, then horizontal, and so on with the rest. But another change may be made, by driving in the end of the 8th cafe two or three ladlefuls of slow fire, to burn till the wheel has stopped its course; then let the other cafes be fixed the contrary way, which will make the wheel run back again: for the cafe at top you may put a small gerbe; and let the cafes on the spokes be short, and filled with a strong brilliant charge.

89. Illuminated Spiral Wheel.

First have a circular horizontal wheel made two feet diameter, with a hole quite through the nave; then take three thin pieces of deal, three feet long each, and $\frac{3}{4}$ of an inch broad each: one end of each of these pieces nail to the fell of the wheel, at an equal distance from one another, and the other end nail to a block with a hole in its bottom, which must be perpendicular with that in the block of the wheel, but not so large. The wheel being thus made, have a hoop planed down very thin and flat; then nail one end of it to the fell of the wheel, and wind it round the three sticks in a spiral line from the wheel to the block at top: on the top of this block fix a cafe of Chinese fire; on the wheel you may place any number of cafes, which must incline downwards, and burn two at a time. If the wheel should consist of 10 cafes, you may let the illuminations and Chinese fire begin with the second cafes. The spindle for this wheel must be a little longer than the cone, and made very smooth at top, on which the upper block is to turn, and the whole weight of the wheel to rest. See fig. 17.

90. Double Spiral Wheel.

For this wheel the block, or nave, must be as long as the height of the worms, or spiral lines, but must be made very thin, and as light as possible. In this block must be fixed several spokes, which must diminish in length, from the wheel to the top, so as not to exceed the surface of a cone of the same height. To the ends of these spokes nail the worms, which must cross each other several times: these worms clothe with illuminations, the same as those on the single wheels; but the horizontal wheel you may clothe as you like. At top of the worm place a cafe of spar-fire, or an amber light. See fig. 18. This figure is shown without leaders, to prevent a confusion of lines.

91. Balloon Wheels,

Are made to turn horizontally: they must be made 2 feet

Of Wheels, &c.

Of Wheels, 2 feet diameter, without any spokes; and very strong, with any number of sides. On the top of a wheel range and fix in pots, 3 inches diameter and 7 inches high each, as many of these as there are cafes on the wheel: near the bottom of each pot make a small vent; into each of these vents carry a leader from the tail of each cafe; some of the pots load with stars, and some with serpents, crackers, &c. As the wheels turn, the pots will successively be fired, and throw into the air a great variety of fires.

92. *Fruiloni Wheel's.*

First have a nave made 9 inches long and 3 in diameter: near the bottom of this nave fix 8 spokes, with a hole in the end of each, large enough to receive a 2 or 4 ounce cafe: each of these spokes may be 14 inches long from the block. Near the top of this block fix 8 more of the same spokes, exactly over the others, but not so long by 2 inches. As this wheel is to run horizontally, all the cafes in the spokes must play obliquely upwards, and all those in the spokes at bottom obliquely downwards. This being done, have a small horizontal wheel made with 8 spokes, each 5 inches long from the block: on the top of this wheel place a cafe of brilliant fire: all the cafes on this wheel must play in an oblique direction downwards, and burn 2 at a time, and those on the large wheel 4 at a time; that is, 2 of those in the top set of spokes, and 2 of those in the bottom set of spokes.

The 4 first cafes on the large wheel, and the 2 first on the small, must be fired at the same time, and the brilliant fire at top at the beginning of the last cafes. The cafes of the wheels may be filled with a grey charge. When these wheels are completed, you must have a strong iron spindle, made 4 feet 6 inches long, and fixed perpendicularly on the top of a stand: on this put the large wheel, whose nave must have a hole quite through from the bottom to the top. This hole must be large enough to turn easy round the bottom of the spindle, at which place there must be a shoulder, to keep the wheel from touching the stand: at the top of the spindle put the small wheel, and join it to a large one with a leader, in order that they may be fired both together.

93. *Cascades of Fire,*

Are made of any size; but one made according to the dimensions of that shown in fig. 1. will be large enough for 8-oz. cafes. Let the distance from A to B be 3 feet; from B to C 2 feet 6 inches; and from C to D 2 feet; and let the cross piece at A be 4 feet long: then from each end of this piece draw a line to D; then make the other cross pieces so long as to come within those lines. The top piece D may be of any length, so as to hold the cafes, at a little distance from each other; all the cross pieces are fixed horizontally, and supported by brackets; the bottom cross piece should be about 1 foot 6 inches broad in the middle, the second 1 foot, the third 9 inches, and the top piece 4 inches: the cafes may be made of any length, but must be filled with a brilliant charge. On the edges of the cross pieces must be nailed bits of wood, with a groove cut in each piece, large enough for a cafe to lie in. These bits of wood are fixed so as to incline downwards, and that the fire from one tier of cafes may play over the other. All the cafes being tied fast on, carry leaders from one to the other; and let there be a

pipe hung from the mouth of one of the cafes, covered at the end with a single paper, which you burn to fire the cascade. Of Wheels, &c.

94. *The Fire-Tree.*

To make a fire-tree, as shewn by fig. 2. you must first have a piece of wood 6 feet long, and 3 inches square; then at E, 9 inches from the top, make a hole in the front, and in each side; or, instead of holes, you may fix short pegs, to fit the inside of the cafes. At F, 9 inches from E, fix 3 more pegs; at G, 1 foot 9 inches from F, fix 3 pegs; at H, 9 inches from G, fix 3 pegs; at I, 9 inches from H, fix 3 pegs, inclining downwards; but all the other pegs must incline upwards, that the cafes may have the same inclination as you see in the figure: then at top place a 4-inch mortar, loaded with stars, rains, or crackers. In the middle of this mortar place a cafe filled with any sort of charge, but let it be fired with the other cafes: a brilliant charge will do for all the cafes; but the mortar may be made of any diameter, and the tree of any size; and on it any number of cafes, provided they are placed in the manner described.

95. *Chinese Fountains.*

To make a Chinese fountain, you must have a perpendicular piece of wood 7 feet long and 2½ inches square. Sixteen inches from the top, fix on the front a cross-piece 1 inch thick, and 2½ broad, with the broad side up: below this, fix 3 more pieces of the same width and thickness, at 16 inches from each other: let the bottom rail be 5 feet long, and the others of such a length as to allow the fire-pumps to stand in the middle of the intervals of each other. The pyramid being thus made, fix in the holes made in the bottom rail 5 fire-pumps, at equal distances; on the 2d rail, place 4 pumps; on the 3d, 3; on the 4th, 2; and on the top of the post, 1; but place them all to incline a little forwards, that, when they throw out the stars, they may not strike against the cross rails. Having fixed your fire-pumps, clothe them with leaders, so that they may all be fired together. See fig. 3.

96. *Of Illuminated Globes with horizontal Wheels.*

The hoops for these globes may be made of wood, tin, or iron wire, about 2 feet diameter. For a single globe take two hoops, and tie them together, one within the other, at right angles; then have a horizontal wheel made, whose diameter must be a little wider than the globe, and its nave 6 inches long; on the top of which the globe is fixed, so as to stand 3 or 4 inches from the wheel: on this wheel you may put any number of cafes, filled with what charge you like; but let two of them burn at a time: they may be placed horizontally, or to incline downwards, just as you choose. Now, when the wheel is clothed, fix on the hoops as many illuminations as will stand within 2½ inches of each other: these you fasten on the hoops with small iron binding wire; and when they are all on, put on your pipes of communication, which must be so managed as to light them all with the 2d or 3d cafe on the wheel. The spindle on which the globe is to run must go through the block of the wheel, up to the inside of the top of the globe; where must be fixed a bit of brass, or iron, with a hole in it to receive the point of the spindle, on which the whole weight of the wheel is to bear, as in fig. 4. which represents a globe on its spindle. By this method may be made a

Of Wheels, crown, which is done by having the hoops bent in the form of a crown. Sometimes globes and crowns are ordered so as to stand still, and the wheel only to turn round; but when you would have the globe or crown to stand still, and the wheel to run by itself, the block of the wheel must not be so long, nor the spindle any longer than to just raise the globe a little above the wheel; and the wheel cases and illumination must begin together.

97. *Dodecaedron,*

So called because it nearly represents a twelve-sided figure, is made thus. First have a ball turned out of some hard wood, 14 inches diameter: when done, divide its surface into 14 equal parts, from which bore holes $1\frac{1}{4}$ inch diameter, perpendicular to the centre, so that they may all meet in the middle: then let there be turned in the inside of each hole a female screw; and to all the holes but one, must be made a round spoke 5 feet long, with 4 inches of the screw at one end to fit the holes; then in the screw-end of all the spokes bore a hole, 5 inches up, which must be bored slanting, so as to come out at one side, a little above the screw; from which cut a small groove along the spoke, within 6 inches of the other end, where you make another hole through to the other side of the spoke. In this end fix a spindle, on which put a small wheel of 3 or 4 sides, each side 6 or 7 inches long: these sides must have grooves cut in them, large enough to receive a 2 or 4 oz. case. When these wheels are clothed, put them on the spindles, and at the end of each spindle put a nut to keep the wheel from falling off. The wheels being thus fixed, carry a pipe from the mouth of the first case on each wheel, through the hole in the side of the spoke, and from thence along the groove, and through the other hole, so as to hang out at the screw-end about an inch. The spokes being all prepared in this manner, you must have a post, on which you intend to fire the work, with an iron screw in the top of it, to fit one of the holes in the ball: on the screw fix the ball; then in the top hole of the ball put a little meal-powder, and some loose quick-match: then screw in all the spokes; and in one side of the ball bore a hole, in which put a leader, and secure it at the end; and your work will be ready to be fired. By this leader the powder and match in the centre is fired, which will light the match at the ends of the spokes all at once, whereby all the wheels will be lighted at once. There may be an addition to this piece, by fixing a small globe on each wheel, or one on the top wheel only. A grey charge will be proper for the wheel-cases.

98. *The Tree of brilliant Fire,*

Is represented by fig. 5. as it appears when burning. First, let A be an upright piece of wood, 4 feet long, 2 inches broad, and 1 thick: at top of this piece, on the flat side, fix a hoop 14 inches diameter; and round its edge and front place illuminations, and in the centre a 5-pointed star; then at E, which is $1\frac{1}{4}$ foot from the edge of the hoop, place 2 cases of brilliant fire, one on each side; these cases should be 1 foot long each: below these fix 2 more cases of the same size, and at such a distance, that their mouths may almost meet them at top: then close to the ends of these cases fix 2 more of the same cases; they must stand parallel to them at E. The cases being thus fixed, clothe them with leaders; so that they,

with the illuminations and stars at top, may all take fire together.

92. *Stars with Points for regulated Pieces, &c.*

These stars are made of different sizes, according to the work for which they are intended: they are made with cases from 1 oz. to 1 lb. but in general with 4 oz. cases, 4 or 5 inches long: the cases must be rolled with paste, and twice as thick of paper as a rocket of the same bore. Having rolled a case, pinch one end of it quite close: then drive in $\frac{1}{4}$ a diameter of clay; and when the case is dry, fill it with composition, 2 or 3 inches to the length of the cases with which it is to burn: at top of the charge drive some clay; as the ends of these cases are seldom pinched, they would be liable to take fire. Having filled a case, divide the circumference of it at the pinched end close to the clay into 5 equal parts; then bore 5 holes with a gimblet, about the size of the neck of a common 4 oz. case, into the composition: from one hole to the other carry a quick-match, and secure it with paper: this paper must be put on in the manner of that on the ends of wheel-cases, so that the hollow part, which projects from the end of the case, may serve to receive a leader from any other work, to give fire to the points of the stars. These stars may be made with any number of points.

100. *Fixed Sun with a transparent Face.*

To make a sun of the best sort, there should be two rows of cases, as in fig. 6. which will show a double glory, and make the rays strong and full. The frame, or sun-wheel, must be made thus: Have a circular flat nave made very strong, 12 inches diameter: to this fix 6 strong flat spokes, A, B, C, D, E, F. On the front of these fix a circular fell, 5 feet diameter; within which fix another fell, the length of one of the sun-cases less in diameter; within this fix a 3d fell, whose diameter must be less than the 2d by the length of 1 case and 1-3d. The wheel being made, divide the fell into so many equal parts as you would have cases (which may be done from 24 to 44): at each division fix a flat iron staple; these staples must be made to fit the cases, to hold them fast on the wheel; let the staples be so placed, that one row of cases may lie in the middle of the intervals of the other.

In the centre of the block of the sun drive a spindle, on which put a small hexagon wheel, whose cases must be filled with the same charge as the cases of the sun: two cases of this wheel must burn at a time, and begin with them on the fells. Having fixed on all the cases, carry pipes of communication from one to the other, as you see in the figure, and from one side of the sun to the wheel in the middle, and from thence to the other side of the sun. These leaders will hold the wheel steady while the sun is fixing up, and will also be a sure method of lighting both cases of the wheel together. A sun thus made is called a *brilliant sun*, because the wood work is entirely covered with fire from the wheel in the middle, so that there appears nothing but sparks of brilliant fire: but if you would have a transparent face in the centre, you must have one made of pasteboard of any size. The method of making a face is, by cutting out the eyes, nose, and mouth, for the sparks of the wheel to appear through; but instead of this face, you may have one painted on oiled paper, or Persian silk, strained tight on a hoop; which

Of Wheels, which hoop must be supported by 3 or 4 pieces of wire at 6 inches distance from the wheel in the centre, so that the light of it may illuminate the face. By this method you may have, in the front of a sun, VIVAR REX, cut in pasteboard, or Apollo painted on silk; but, for a small collection, a sun with a single glory, and a wheel in front, will be most suitable. Half-pound cafes, filled 10 inches with composition, will be a good size for a sun of 5 feet diameter; but, if larger, the cafes must be greater in proportion.

101. *Three Vertical Wheels illuminated, which turn on their own Naves upon a horizontal Table.*

A plan of this is shown by fig. 7. Let D be a deal table 3 feet in diameter: this table must be fixed horizontally on the top of a post; on this post must be a perpendicular iron spindle, which must come through the centre of the table: then let A, B, C, be 3 spokes joined to a triangular flat piece of wood, in the middle of which make a hole to fit easily over the spindle: let E, F, G, be pieces of wood, 4 or 5 inches long each, and 2 inches square, fixed on the under sides of the spokes; in these pieces make holes lengthwise to receive the thin part of the blocks of the wheels, which, when in, are prevented from coming out by a small iron pin being run through the end of each. K, L, M, are three vertical octagon wheels, 18 inches diameter each: the blocks of these wheels must be long enough for 3 or 4 inches to rest on the table; round which part drive a number of sharp points of wire, which must not project out of the blocks more than 1-16th of an inch: the use of these points is, that, when the blocks run round, they will stick in the table, and help the wheels forward: if the naves are made of strong wood, one inch will be enough for the diameter of the thin part, which should be made to turn easy in the holes in the pieces E, F, G. On the front of the wheels make 4 or 5 circles of strong wire, or flat hoops, and tie on them as many illuminations as they will hold at 2 inches from each other: instead of circles, you may make spiral lines, clothed with illuminations, at the same distance from each other as those on the hoops. When illuminations are fixed on a spiral line in the front of a wheel, they must be placed a little on the slant, the contrary way that the wheel runs: the cafes for these wheels may be filled with any coloured charge, but must burn only one at a time.

The wheels being thus prepared, you must have a globe, crown, or spiral wheel, to put on the spindle in the middle of the table: this spindle should be just long enough to raise the wheel of the globe, crown, or spiral wheel, so high that its fire may play over the 3 vertical wheels: by this means their fires will not be confused, nor will the wheels receive any damage from the fire of each other. In clothing this work, let the leaders be so managed, that all the wheels may light together, and the illuminations after 2 cafes of each wheel are burned.

102. *Illuminated Chandelier.*

Illuminated works are much admired by the Italians, and indeed are a great addition to a collection of works: in a grand exhibition an illuminated piece should be fired after every two or three wheels, or fixed pieces of common and brilliant fires; and likewise illuminated works may be made cheap, quick, and easy.

To make an illuminated chandelier, you must first have one made of thin wood (see fig. 8.) The chandelier being made, bore in the front of the branches, and in the body, and also in the crown at top, as many holes for illuminations as they will contain at 3 inches distance from each other: in these holes put illuminations filled with white, blue, or brilliant charge. Having fixed in the port-fires, clothe them with leaders, so that the chandelier and crown may light together. The small circles on this figure represent the mouths of the illuminations, which must project straight from the front.

103. *Illuminated Yew Tree.*

First have a tree made of wood, such as is shown by fig. 9. The middle piece or stem, on which the branches are fixed, must be 8 feet 6 inches high: at the bottom of this piece draw a line, at right angles, 2 feet 6 inches long at each side; then from L, which is 1 foot 6 inches from the bottom, draw a line on each side to C and D: these lines will give the length of the two first branches. Then put on the two top branches parallel to them at bottom: let the length of each of these branches be 1 foot from the stem: from the ends of these two branches draw a line to C and D: then fix on 5 more branches at an equal distance from each other, and their length will be determined by the lines AC and ED. When the branches are fixed, place illuminating portfires on the top of each, as many as you choose: behind the top of the stem fasten a gerbe or white fountain, which must be fired at the beginning of the illuminations on the tree.

104. *Flaming Stars with brilliant Wheels.*

To make a flaming star, you must first have made a circular piece of strong wood about 1 inch thick and 2 feet diameter: round this block fix 8 points, 2 feet 6 inches long each; 4 of these points must be straight and 4 flaming: these points being joined on very strong, and even with the surface of the block, nail tin or pasteboard on their edges, from the block to the end of each, where they must be joined: this tin must project in front 8 inches, and be joined where they meet at the block; round the front of the block fix 4 pieces of thick iron wire, 8 inches long each, equally distant from each other: this being done, cut a piece of pasteboard round, 2 feet diameter, and draw on it a star, as may be seen in fig. 10. Cut out this star, and on the back of it paste oiled paper; then paint each point half red and half yellow, lengthwise; but the body of the star must be left open, wherein must run a brilliant wheel, made thus: Have a light block turned 9 inches long: at each end of it fix 6 spokes; at the end of each spoke put a 2 ounce cafe of brilliant fire: the length of these cafes must be in proportion to the wheel, and the diameter of the wheel when the cafes are on must be a little less than the diameter of the body of the small star: the cafes on the spokes in front must have their mouths incline outwards, and those on the inside spokes must be placed so as to form a vertical circle of fire. When you place your leaders, carry the first pipe from the tail of 1 of the cafes in front to the mouth of 1 of the inside cafes, and from the tail of that to another in front, and so on to all the cafes. Your wheel being made, put it on a spindle, in the centre of the star; this spindle must have a shoulder at bottom, to keep the wheel at a little distance from the block. This wheel must be kept on the

Of Wheels, the spindle by a nut at the end; having fixed on the wheel, fasten the transparent star to the 4 pieces of wire: when you fire it, you will only see a common horizontal wheel; but when the first case is burnt out, it will fire one of the vertical cases, which will show the transparent star, and fill the large flames and points with fire; then it will again appear like a common wheel, and so on for 12 changes.

105. *Projected regulated Piece of nine Mutations.*

A regulated piece, if well executed, is as curious as any in fire-works: it consists of fixed and moveable pieces on one spindle, representing various figures, which take fire successively one from another, without any assistance after lighting the first mutation. See fig. 11.

I. Names of the mutations, with the colour of fire and size of the cases belonging to each.

First mutation is a hexagon vertical wheel, illuminated in front with small portfires tied on the spokes; this wheel must be clothed with 2 ounce cases, filled with black charge; the length of these cases is determined by the size of the wheel, but must burn singly.

Second mutation is a fixed piece, called a *golden glory*, by reason of the cases being filled with spur-fire. The cases must stand perpendicular to the block on which they are fixed, so that, when burning, they may represent a glory of fire. This mutation is generally composed of 5 or 7 two ounce cases.

Third mutation is moveable; and is only an octagon vertical wheel, clothed with 4 ounce cases, filled with brilliant charge: 2 of these cases must burn at a time. In this wheel you may make changes of fire.

Fourth mutation, is a fixed fun of brilliant fire, consisting of 12 four ounce cases: the necks of these cases must be a little larger than those of 4 ounce wheel-cases. In this mutation may be made a change of fire, by filling the cases half with brilliant charge, and half with grey.

Fifth mutation, is a fixed piece, called the *porcupine's quills*. This piece consists of 12 spokes, standing perpendicular to the block in which they are fixed; on each of these spokes, near the end, must be placed a 4 ounce case of brilliant fire. All these cases must incline either to the right or left, so that they may all play one way.

Sixth mutation, is a standing piece, called the *cross fire*. This mutation consists of 8 spokes fixed in a block; near the end of each of those spokes must be tied two 4 ounce cases of white charge, one across the other, so that the fires from the cases on one spoke may intersect the fire from the cases on the other.

Seventh mutation, is a fixed wheel, with 2 circular fells, on which are placed 16 eight-ounce cases of brilliant fire, in the form of a star. This piece is called a *fixed star of will-fire*.

Eighth mutation. This is a beautiful piece, called a *brilliant star-piece*. It consists of 6 spokes, which are strengthened by 2 fells of a hexagon form, at some distance from each other; at the end of each spoke, in the front, is fixed a brilliant star of 5 points; and on each side of every star is placed a 4 ounce case of black or grey charge; these cases must be placed with their mouths sidewise, so that their fires may cross each other.

Ninth mutation, is a wheel-piece. This is composed of 6 long spokes, with a hexagon vertical wheel at the end of each; these wheels run on spindles in the front of the spokes; all the wheels are lighted together: 2 ounce cases will do for these wheels, and may be filled with any coloured charge.

II. Proportions of the mutations, with the method of conveying the fire from one to the other, and the distance they stand one from the other on the spindle.

First Mutation, must be a hexagon vertical wheel, 14 inches diameter; on one side of the block, whose diameter is $2\frac{1}{4}$ inches, is fixed a tin barrel A (see fig. 11. n^o 1.) This barrel must be a little less in diameter than the nave; let the length of the barrel and block be 6 inches. Having fixed the cases on the wheel, carry a leader from the tail of the last case into the tin-barrel through a hole made on purpose, 2 inches from the block; at the end of this leader let there be about 1 inch or 2 of loose match; but take care to secure well the hole wherein the pipe is put, to prevent any sparks falling in, which would light the second mutation before its time, and confuse the whole.

Second mutation is thus made. Have a nave turned $2\frac{1}{2}$ inches diameter, and 3 long; then let $\frac{1}{2}$ an inch of that end which faces the first wheel be turned so as to fit easy into the tin barrel of the first mutation, which must turn round it without touching. On the other end of the block fix a tin barrel B, n^o 2. This barrel must be 6 inches long, and only half an inch of it to fit on the block. Round the nave fix 5 spokes, $1\frac{1}{2}$ inch long each; the diameter of the spokes must be equal to a 2 oz. former. On these spokes put five 7-inch 2 oz. cases of spur-fire, and carry leaders from the mouth of one to the other, that they may all light together. Then from the mouth of one of the cases carry a leader through a hole bored slantwise in the nave, from between the spokes, to the front of the block near the spindle hole: the end of this leader must project out of the hole into the barrel of the first mutation, so that when the pipe which comes from the end of the last case on the first wheel flashes, it may take fire, and light the 2d mutation. To communicate the fire to the 3d mutation, bore a hole near the bottom of one of the 5 cases to the composition, and from thence carry a leader into a hole made in the middle of the barrel B: this hole must be covered with pasted paper.

Third mutation, may be either an octagon or hexagon wheel, 20 inches diameter; let the nave be $3\frac{1}{4}$ inches diameter, and $3\frac{1}{2}$ in length; $1\frac{1}{2}$ inch of the front of the nave must be made to fit in the barrel B. On the other end of the block fix a tin barrel C, n^o 3. This barrel must be $6\frac{1}{2}$ inches in length, one inch of which must fit over the block. The cases of this wheel must burn 2 at a time; and from the mouths of the 2 first cases carry a leader, through holes in the nave, into the barrel of the second mutation, after the usual manner: but besides these leaders let a pipe go across the wheel from one first case to the other; then from the tail of one of the last cases carry a pipe into a hole in the middle of the barrel C: at the end of this pipe let there be some loose quick match.

Fourth and fifth mutations. These may be described under

Of Wheels,
&c.

Of Wheels, under one head, as their naves are made of one piece, which from E to F is 14 inches; E, a block 4 inches diameter, with 10 or 12 short spokes, on which are fixed 11-inch 8-oz. cafes: let the front of this block be made to fit easy in the barrel C, and clothe the cafes so that they may all light together; and let a pipe be carried through a hole in the block into the barrel C, in order to receive the fire from the leader brought from the last cafe on the wheel. G is the nave of the 5th mutation, whose diameter must be 4 $\frac{1}{2}$ inches: in this nave fix 10 or 12 spokes, 1 $\frac{1}{2}$ foot in length each; these spokes must stand 7 inches distant from the spokes of the 4th mutation; and at the end of each spoke tie a 4-oz. cafe, as n^o 5. All these cafes are to be lighted together, by a leader brought from the end of one of the cafes on n^o 4. Let F and H be of the same piece of wood as E and G, but as much thinner as possible, to make the work light.

Sixth and seventh mutations. The blocks of these 2 mutations are turned out of one piece of wood, whose length from F to P is 15 inches. L, a block 5 inches diameter, in which are fixed 8 spokes, each 2 feet 4 inches long; at the end of each spoke tie two 4-oz. cafes, as n^o 6. All these cafes must be fired at the same time, by a pipe brought from the end of one of the cafes on the 5th mutation. Let the distance between the spokes at L, and those in the 5th mutation, be 7 inches. M, the nave of the 7th mutation, whose diameter must be 5 $\frac{1}{2}$ inches: in this nave fix 8 spokes, and on the front of them 2 circular fells, one of 4 feet 8 inches diameter, and one of 3 feet 11 inches diameter; on these fells tie 16 8-oz. or pound cafes, as in n^o 7. and carry leaders from one to the other, so that they may be all fired together. This mutation must be fired by a leader brought from the tail of one of the cafes on the 6th mutation.

Eighth and ninth mutations. The blocks of these may be turned out of one piece, whose length from P to D must be 12 inches. O, the block of the 8th mutation, which must be 6 inches diameter; and in it must be fixed 6 spokes, each 3 feet in length, strengthened by an hexagon fell within 3 or 4 inches of the ends of the spokes: close to the end of each spoke, in the front, fix a five-pointed brilliant star; then 7 inches below each star tie two 10-inch 8 oz. cafes, so that the upper ends of the cafes may rest on the fells, and their ends on the spokes. Each of these cafes must be placed parallel to the opposite fell (see n^o 8.) N N N, &c. are the cafes, and k k k, &c. the stars.

The 9th mutation is thus made. Let D be a block 7 inches diameter. In this block must be screwed 6 spokes, 6 feet long each, with holes and grooves for leaders, as those in the dodecaedron; at the end of each spoke, in the front, fix a spindle for a hexagon vertical wheel, 10 inches diameter, as in n^o 9. When these wheels are on, carry a leader from each into the block, so that they may all meet; then lead a pipe from the end of one of the cafes of the 8th mutation, through a hole bored in the block D, to meet the leaders from the vertical wheels, so that they may all be fired together.

The spindles for larger pieces are required to be made very strong, and as exact as possible: for a piece of 9 mutations, let the spindle be at the large end 1 inch diameter, and continue that thickness as far as the

7th mutation; and thence to the 5th, let its diameter be $\frac{3}{4}$ of an inch; from the 5th to the 4th, 5-8ths of an inch; from the 4th to the 2d, $\frac{1}{2}$ inch; and from the 2d to the end, 3-8ths of an inch. At the small end must be a nut to keep on the first wheel, and at the thick end must be a large nut, as shown by the figure; so that the screw part of the spindle being put through a post, and a nut screwed on tight, the spindle will be held fast and steady: but you are to observe, that that part of the spindle on which the moveable pieces are to run, be made long enough for the wheels to run easy without sticking; the fixed pieces being made on different blocks, the leaders must be joined, after they are fixed on the spindle. The best method of preventing the fixed mutations from moving on the spindle, is to make that part of the spindle which goes through them square; but as it would be difficult to make square holes through such long blocks as are sometimes required, it will be best to make them thus: Bore a hole a little larger than the diameter of the spindle; and at each end of the block, over the hole, fasten a piece of brass with a square hole in it to fit the spindle.

106. *To make an Horizontal Wheel change to a Vertical Wheel with a Sun in front.*

The sudden change of this piece is very pleasing; and gives great surprise to those who are not acquainted with the contrivance. A wheel for this purpose should be about three feet diameter, and its fell circular; on which tie 16 half pound cafes filled with brilliant charge: two of these cafes must burn at a time; and on each end of the nave must be a tin barrel of the same construction as those on the regulated piece. The wheel being completed, prepare the post or stand thus: First have a stand made of any height, about three or four inches square; then saw off from the top a piece two feet long; this piece join again at the place where it was cut, with a hinge on one side, so that it may lift up and down in the front of the stand; then fix on the top of the bottom-part of the stand, on each side, a bracket; which bracket must project at right angles with the stand, one foot from the front, for the short piece to rest on. These brackets must be placed a little above the joint of the post, so that when the upper stand falls, it may lie between them at right angles with the bottom stand; which may be done by fixing a piece of wood, one foot long, between the brackets, and even with the top of the bottom stand; then, as the brackets rise above the bottom stand, they will form a channel for the short post to lie in, and keep it steady without straining the hinge. On the side of the short post, opposite the hinge, nail a piece of wood, of such a length, that, when the post is perpendicular, it may reach about 1 $\frac{1}{2}$ feet down the long post; to which being tied, it will hold the short stand upright. The stand being thus prepared, in the top of it fix a spindle 10 inches long: on this spindle put the wheel: then fix on a brilliant sun with a single glory; the diameter of this sun must be 6 inches less than that of the wheel. When you fire this piece, light the wheel first, and let it run horizontally till four cafes are consumed: then from the end of the fourth cafe carry a leader into the tin barrel that turns over the end of the stand: this leader must be met by another brought through the top of the post, from a cafe filled with a strong

Of Wheels, &c. port-fire charge, and tied to the bottom post, with its mouth facing the packthread which holds up the stand; so that when this case is lighted, it will burn the packthread, and let the wheel fall forward, by which means it will become vertical: then from the last case of the wheel, carry a leader into the barrel next the sun, which will begin as soon as the wheel is burnt out.

107. *Grand Volute illuminated with a projected Wheel in front.*

Plate
CCCCXXI.

First have two hoops made of strong iron wire, one of 6 feet diameter, and one of 4 feet 2 inches; these hoops must be joined to scrolls A, A, A, &c. as in fig. 1. These scrolls must be made of the same sort of wire as the hoops; on these scrolls tie, with iron-binding wire, as many illuminating port-fires as they will hold, at two inches distance; clothe these port-fires with leaders, so that they may all take fire together.—Then let C be a circular wheel of four spokes, 3 feet 6 inches diameter; and on its fell tie as many 4-oz. cafes, head to tail, as will complete the circle, only allowing a sufficient distance between the cafes, that the fire may pass free; which may be done by cutting the upper part of the end of each case a little shelving: on each spoke fix a 4-oz. case, about three inches from the fell of the wheel: these cafes are to burn one at a time, and the first of them to begin with those on the fell, of which four are to burn at a time; so that the wheel will last no longer than $\frac{1}{4}$ of the cafes on the fell, which in number should be 16 or 20. On the front of the wheel form a spiral line with strong wire, on which tie port-fires, placing them on a slant, with their mouths to face the same way as the cafes on the wheel: all these port-fires must be fired with the second cafes of the wheel. Let D, D, D, &c. be spokes of wood, all made to screw into a block in the centre; each of these spokes may be in length about 4 feet 6 inches; in the top of each fix a spindle, and on each spindle put a spiral wheel of 8 spokes, such as E, E, E, &c. The blocks of these wheels must have a hole at top for the centre cafes, and the spindle must have nuts screwed on their ends; which nuts should fit in the holes at top of the blocks, so that all the wheels must be put on before you fix in the centre cafes: as some of these wheels, by reason of their situation, will not bear on the nut, it will be necessary to have smooth shoulders made on the spindles for the blocks to run on. The cafes of these wheels are to burn double; and the method of firing them, is by carrying a leader from each down the spokes into the block in the centre, as in the dodecaedron, but the centre case of each wheel must begin with the two last cafes as usual. It is to be observed, that the large circular wheel in front must have a tin barrel on its block, into which a pipe must be carried from one of the second cafes on the wheel; this pipe being met by another from the large block, in which the 8 spokes are screwed, will fire all the spiral wheels and the illuminating port-fires at the same time. The cafes of the projected wheel may be filled with a white charge, and those of the spiral wheels with a grey.

108. *Moon and Seven Stars.*

Let fig. 2. be a smooth circular board 6 feet diameter: out of the middle of it cut a circular piece 12 or 14 inches diameter; and over the vacancy put white Persian silk, on which paint a moon's face: then let

I, I, I, &c. be stars, each 4 or 5 inches diameter, cut out with five points, and covered with oiled silk: on the front of the large circular board draw a 7-pointed star, as large as the circle will allow; then on the lines which form this star, bore holes, wherein fix pointed stars. When this case is to be fired, it must be fixed upon the front of a post, on a spindle, with a wheel of brilliant fire behind the face of the moon: so that, while the wheel burns, the moon and stars will appear transparent: and when the wheel has burnt out, they will disappear, and the large star in front, which is formed of pointed stars, will begin, being lighted by a pipe of communication from the last case of the vertical wheel, behind the moon; this pipe must be managed in the same manner as those in regulated pieces.

109. *Double Cone-Wheel illuminated.*

This piece is represented by fig. 3. Let A be a strong decagon wheel, 2 feet 6 inches diameter; then on each side of it fix a cone B and C: these cones are to consist of a number of hoops, supported by 3 or 4 pieces of wood, in the manner of the spiral wheels. Let the height of each cone be 3 feet 6 inches; and on all the hoops tie port-fires horizontally, with their mouths outwards, and clothe the wheel with 8-oz. cafes, all to play horizontally, two at a time: the cones may be fired with the first or second cafes. The spindle for this piece must go through both the cones, and rise three feet above the point of the cone at top; so that its length will be 10 feet 4 inches from the top of the post H, in which it is fixed, allowing four inches for the thickness of the block of the wheel. The whole weight of the wheel and cones must bear on a shoulder in the spindle, on which the block of the wheel must turn.—Near the top of the spindle must be a hole in the front, into which screw a small spindle, after the cones are on: then on this small spindle fix a sun D, composed of sixteen 9-inch 4-oz. cafes of brilliant fire; which cafes must not be placed on a fell, but only stuck into a block of 6 inches diameter: then in the front of this sun must be a circular vertical wheel, 16 inches diameter; on the front of this wheel form with iron-wire a spiral line, and clothe it with illuminations after the usual method. As this wheel is not to be fired till the cones are burnt out, the method of firing it is thus: Let the hole in the block, at the top of the uppermost cone, be a little larger than the spindle which passes through it. Then, from the first case of the vertical wheel before the sun, carry a leader down the side of the spindle to the top of the block of the horizontal wheel, on which must be a tin barrel: then this leader being met by another brought from the end of the last case of the horizontal wheel, will give fire to the vertical wheel so soon as the cones are extinguished: but the sun D must not be fired till the vertical wheel is quite burnt out.

110. *Fire-pumps.*

Cases for fire-pumps are made as those for tourbillons; only they are patted, instead of being rolled dry. Having rolled and dried your cafes, fill them: first put in a little meal-powder, and then a star; on which ram lightly a ladle or two of composition, then a little meal-powder, and on that a star, then again composition; and so on till you have filled the case. Stars for fire-pumps should not be round; but must be made either square, or flat and circular, with a hole through the middle:

Wheels,
&c.

middle : the quantity of powder for throwing the stars must increase as you come near the top of the case ; for, if much powder be put at the bottom, it will burst the case. The stars must differ in size in this manner : Let the star which you put in first be about $\frac{1}{4}$ less than the bore of the case ; but let the next star be a little larger, and the third star a little larger than the second, and so on : let them increase in diameter till within two of the top of the case, which two must fit in tight. As the loading of fire-pumps is somewhat difficult, it will be necessary to make two or three trials before you depend on their performance : when you fill a number of pumps, take care not to put in each an equal quantity of charge between the stars, so that when they are fired, they may not throw up too many stars together. Cases for fire-pumps should be made very strong, and rolled on 4 or 8 oz. formers, 10 or 12 inches long each.

111. *Vertical Scroll Wheel.*Plate
cccccxi.

This wheel may be made of any diameter, but must be constructed as in fig. 4. to do which proceed thus : Have a block made of a moderate size, in which fix four flat spokes, and on them fix a flat circular fell of wood ; round the front of this fell place port-fires ; then on the front of the spokes form a scroll, either with a hoop or strong iron wire ; on this scroll tie cases of brilliant fire, in proportion to the wheel, head to tail, as in the figure. When you fire this wheel, light the first case near the fell ; then, as the cases fire successively, you will see the circle of fire gradually diminish : but whether the illuminations on the fell begin with the scroll or not, is immaterial, that being left entirely to the maker.

N. B. This wheel may be put in the front of a regulated piece, or fired by itself, occasionally.

112. *Pin-Wheels.*

First roll some paper pipes, about fourteen inches long each ; these pipes must not be made thick of paper, two or three rounds of elephant paper being sufficient. When your pipes are thoroughly dried, you must have a tin tube 12 inches long, to fit easy into the pipes ; at one end of this tube fix a small conical cup, which cone is called a *funnel* ; then bend one end of one of the pipes, and put the funnel in at the other as far as it will reach, and fill the cup with composition : then draw out the funnel by a little at a time, shaking it up and down, and it will fill the pipe as it comes out. Having filled some pipes, have some small blocks made about one inch diameter and half an inch thick : round one of these blocks wind and paste a pipe, and to the end of this pipe join another ; which must be done by twisting the end of one pipe to a point, and putting it into the end of the other with a little paste : in this manner join four or five pipes, winding them one upon the other so as to form a spiral line. Having wound on your pipes, paste two slips of paper across them to hold them together : besides these slips of paper, the pipes must be pasted together.

There is another method of making these wheels, viz. by winding on the pipes without paste, and sticking them together with sealing-wax at every half turn ; so that when they are fired, the end will fall loose every time the fire passes the wax, by which means the circle of fire will be considerably increased. The formers for these pipes are made from $\frac{1}{2}$ to $\frac{1}{16}$ ths of an inch

diameter ; and the composition for them is as follows : Meal-powder 8 oz. saltpetre 2 oz. and sulphur 1 : among these ingredients may be mixed a little steel-filings or the dust of cast iron : this composition should be very dry, and not made too fine, or it will stick in the funnel. These wheels may be fired on a large pin, and held in the hand with safety.

113. *Fire-globes.*

There are two sorts of fire-globes ; one with projected cases ; the other with the cases concealed, thus : Have a globe made of wood, of any diameter you choose, and divide the surface of it into 14 equal parts, and at each division bore a hole perpendicular to the centre : these holes must be in proportion to the cases intended to be used : in every hole except one, put a case filled with brilliant, or any other charge, and let the mouths of the cases be even with the surface of the globe ; then cut in the globe a groove, from the mouth of one case to the other, for leaders, which must be carried from case to case, so that they may all be fired together ; this done, cover the globe with a single paper, and paint it. These globes may be used to ornament a building.

Fire-globes with projected cases are made thus : Your globe being made with 14 holes bored in it as usual, fix in every hole except one, a case, and let each case project from the globe two-thirds of its length ; then clothe all the cases with leaders, so that they may all take fire at the same time. Fire-globes are supported by a pintle, made to fit the hole in which there is no case.

114. *To thread and join Leaders, and place them on different Works.*

Joining and placing leaders is a very essential part of fire-works, as it is on the leaders that the performance of all complex works depends ; for which reason the method of conducting pipes of communication shall be here explained in as plain a manner as possible. Your works being ready to be clothed, proceed thus : Cut your pipes of a sufficient length to reach from one case to the other ; then put in the quick-match, which must always be made to go in very easy : when the match is in, cut it off within about an inch of the end of the pipe, and let it project as much at the other end ; then fasten the pipe to the mouth of each case with a pin, and put the loose ends of the match into the mouths of the cases, with a little meal-powder : this done to all the cases, paste over the mouth of each two or three bits of paper. The preceding method is used for large cases, and the following for small, and for illuminations : First thread a long pipe ; then lay it on the tops of the cases, and cut a bit of the under side, over the mouth of each case, so that the match may appear : then pin the pipe to every other case ; but before you put on the pipes, put a little meal-powder in the mouth of each case. If the cases thus clothed are port-fires on illuminated works, cover the mouth of each case with a single paper ; but if they are choaked cases, situated so that a number of sparks from other works may fall on them before they are fired, secure them with three or four papers, which must be pasted on very smooth, that there may be no creases for the sparks to lodge in, which often set fire to the works before their time. Avoid as much as possible placing the leaders too near, or one across the other so as to touch, as it may happen that the flash of one

Different
Pieces of
Fire-works

will fire the other; therefore if your works should be so formed that the leaders must cross or touch, be sure to make them very strong, and secure at the joints, and at every opening.

When a great length of pipe is required, it must be made by joining several pipes in this manner: Having put on one length of match as many pipes as it will hold, paste paper over every joint; but, if a still greater length is required, more pipes must be joined, by cutting about an inch off one side of each pipe near the end, and laying the quick-match together, and tying them fast with small twine; after which, cover the joining with pasted paper.

115. *Placing Fire-works to be exhibited.*

Nothing adds more to the appearance of fire-works than the placing them properly; though the manner of placing them chiefly depends on the judgment of the maker. The following are the rules generally observed, whether the works are to be fired on a building or on stands: If they are a double set, place one wheel of a sort on each side of the building; and next to each of them, towards the centre, place a fixed piece, then wheels, and so on; leaving a sufficient distance between them for the fire to play from one without burning the other. Having fixed some of your works thus in front, place the rest behind them, in the centre of their intervals: The largest piece, which is generally a regulated or transparent piece, must be placed in the centre of the building, and behind it a gun, which must always stand above all the other works: A little before the building, or stands, place your large gerbes; and at the back of the works fix your marron batteries, *pots des aigrettes*, *pots des brins*, *pots des saucissons*, air-balloons, and flights of rockets: The rocket stands may be fixed behind, or anywhere else, so as not to be in the way of the works.

Single collections are fired on stands; which stands are made in the same manner as theodolite stands, only the top part must be long or short occasionally: these stands may be fixed up very soon without much trouble.

116. *Order of Firing.*

1. Two signal
2. Six sky
3. Two honorary
4. Four caduceus
5. } Two { vertical } wheels illuminated
6. } { spiral }
7. } { transparent stars }
8. A line rocket of five changes
9. Four tourbillons
10. } horizontal wheels
11. } air balloons illuminated
12. } Two { Chinese fountains
13. } { regulating pieces of four mutations each
14. } { pots des aigrettes }
15. Three large gerbes
16. A flight of rockets
17. } Two { balloon wheels
18. } { cascades of brilliant fire
19. Twelve sky-rockets.
20. } Two { illuminated yew trees
21. } { air-balloons of serpents, and 2 compound
22. Four tourbillons.

Different
Pieces of
Fire-works

23. } Two { Fruiloni wheels
24. } { illuminated globes with horizontal wheels
25. One pot des saucissons
26. Two plural wheels
27. Marron battery
28. Two chandeliers illuminated
29. Range of pots des brins
30. Twelve sky-rockets
31. Two yew-trees of fire
32. Nest of serpents
33. Two double cones illuminated
34. Regulating piece of seven mutations, viz.
 1. Vertical wheel illuminated
 2. Golden glory
 3. Octagon vertical wheel
 4. Porcupine's quills
 5. Cross fires
 6. Star-piece with brilliant rays
 7. Six vertical wheels
35. Brilliant gun
36. Large flight of rockets.

When water-works are to be exhibited, divide them into several sets, and fire one set after every fifth or sixth change of land and air-works. Observe this rule in firing a double set of works: Always begin with sky-rockets, then two moveable pieces, then two fixed pieces, and so on; ending with a large flight of rockets, or a marron battery: if a single collection, fire a fixed piece after every wheel or two, and now and then some air and water-works.

117. *Fountain of Sky-rockets.*

Fig. 5. represents a fountain of 30 rockets. Let Plate
A be a perpendicular post, 15 feet high from the ground, and 4 inches square. Let the rail, or cross-piece C, be 1 foot 6 inches long, 3 inches broad, and 1 thick. The rail D, at bottom, must be 6 feet long, 1 foot broad, and 1 inch thick. F and G are the two sides which serve to supply the rails D, E, H, I, C: these sides are 1 foot broad at bottom, and cut in the front with a regular slope, to 3 inches at top; but their back edges must be parallel with the front of the pots A. The breadth of the rails E, H, I, will be determined by the breadth of the sides: all the rails must be fixed at 2 feet distance from each other, and at right angles with the pots. Having placed the rails thus, bore in the bottom rail 10 holes, at equal distances, large enough to receive the stick of a one-pound rocket: in the back edge of this rail cut a groove from one end to the other, fit to contain a quick-match; then cut a groove in the top of the rail, from the edge of each hole, into the groove in the back: in the same manner cut in the second rail, E, 8 holes and grooves; in the third rail, H, 6 holes and grooves; in the fourth rail, I, 4 holes and grooves; and in the top rail, 2 holes and grooves. B, a rail with holes in it to guide the ends of the rocket-sticks: this rail must be fixed 6 feet from the rail D. The fountain frame being thus made, prepare your rockets thus: Tie round the mouth of each a piece of thin paper, large enough to go twice round, and to project about $1\frac{1}{2}$ inch from the mouth of the rocket, which must be rubbed with wet meal-powder; in the mouth of each rocket put a leader, which secure well with the paper that projects from the mouth of the case: these leaders must be carried into the grooves in

Different
Pieces of
Fire-works

in the back of the rails, in which lay a quick-match from one end to the other, and cover it with pasted paper: holes must be made in the rail D, to receive the ends of the sticks of the rockets in the rail E, and so on to the fourth rail; so that the sticks of the rockets at top will go through all the rails. The rockets being so prepared, fix a gerbe, or white flower-pot, on each rail, before the post, with their mouths inclining a little forwards: these gerbes must be lighted all at once. Behind or before each gerbe, fix a case of brilliant or flow fire: these cases must be filled so that they may burn out one after the other, to regulate the fountain; which may be done by carrying a leader from the end of each flow or brilliant fire, into the groove in the back of each rail. Different fixed rockets may be used in these fountains: but it will be best to fill the heads of the rockets on each rail with different sorts of things, in this manner; those at top with crackers, the next with rains, the third with serpents, the fourth with tailed stars, and the last flight with common or brilliant stars.

118. *Palm Tree.*

This piece, though made of common fires, and of a simple construction, has a very pleasing effect; owing to the fires intersecting so often, that they resemble the branches of trees. Let A (fig. 6.) be a perpendicular post, of any thickness, so that it is sufficiently strong to hold the cases; let the distance from B to C be 2 feet 6 inches, and C to D 2 feet 6 inches, and let the length of each cross piece be 2 feet; on each end of each fix a five-pointed star: then fix, on pegs made on purpose, 12-inch half-pound cases of brilliant fire, as in the figure. All the cases and stars must be fired at once. This piece should be fixed high from the ground.

119. *Illuminated Pyramid, with Archimedian Screws, a Globe, and vertical Sun,*

May be of any size. One made according to the dimensions of fig. 7. will be a good proportion, whose height is 21 feet; from C to D, 6 feet; from E to F, 9 feet: the space between the rails must be 6 inches, and the rails as thin as possible: in all the rails stick port-fires at four inches distance. The Archimedian screws, G, K, are nothing more than double spiral wheels, with the cases placed on their wheels horizontally instead of obliquely. The vertical sun, I, need not consist of more than 12 rays, to form a single glory. The globe at top must be made in proportion to the pyramid; which being prepared according to the preceding directions, place your leaders so that all the illuminating port-fires, screws, globe, and sun, may take fire together. The pyramid must be supported by the two sides, and by a support brought from a pole, which must be placed two feet from the back of the pyramid, that the wheels may run free.

120. *Rose piece and Sun.*

A rose-piece may be used for a mutation of a regulated piece, or fired by itself: it makes the best appearance when made large; if its exterior diameter be 6 feet, it will be a good size. Fig. 8 shows the manner it appears in before it is fired. Let the exterior fell be made of wood, and supported by 4 wooden spokes: all the other parts, on which the illuminations are fixed, must be made of strong iron wire: on the exterior fell place as many half-pound cases of brilliant charge as you think proper, but the more the better;

for the nearer the cases are placed, the stronger will be the rays of the sun: the illuminations should be placed within 3 inches of each other: they must all be fired together, and burn some time before the sun is lighted; which may be done by carrying a leader from the middle of one of the illuminations, to the mouth of one of the sun cases.

121. *Transparent Stars with illuminated Rays.*

Fig. 9. represents an illuminated star. Let the diameter from A to B be 2 feet, and from C to D 7 feet. First make a strong circular back or body of the star, 2 feet diameter, to which you fix the illuminated rays: in the centre of the front of the body fix a spindle, on which put a double triangular wheel, 6 inches diameter, clothed with 2 ounce cases of brilliant charge: the cases on this wheel must burn but one at a time. Round the edge of the body nail a hoop made of thin wood or tin: this hoop must project in front 6 or 7 inches: in this hoop cut 3 or 4 holes to let out the smoke from the wheel. The star and garter may be cut out of strong pasteboard or tin, made in this manner: Cut a round piece of pasteboard or tin, 2 feet diameter, on which draw a star, and cut it out; then over the vacancy paste Persian silk; paint the letters yellow; 4 of the rays yellow, and 4 red; the crosses in the middle may be painted half red and half yellow, or yellow and blue. This transparent star must be fastened to the wooden hoop by a screw, to take off and on; the illuminated rays are made of thin wood, with tin sockets fixed on their sides within 4 inches of each other; in these sockets stick illuminating port-fires; behind the point of each ray fix a half-pound case of grey, black, or Chinese fire.

N. B. The illuminated rays to be lighted at the same time as the triangular wheel, or after it is burnt out; which may be done by a tin barrel being fixed to the wheel, after the manner of those in the regulated pieces. Into this barrel carry a leader from the illuminated rays, through the back of the star; which leader must be met by another, brought from the tail of the last case on the wheel.

122. *Transparent Table Star illuminated.*

Fig. 1. represents a table star, whose diameter, from E to F, is 12 feet; and from E to I, 4 feet. This proportion, observed on each side, will make the centre frame 4 feet square: in this square fix a transparent star, as in the figure. This star may be painted blue, and its rays made as those of the flaming stars described before. The wheel for this star may be composed of different coloured fires, with a charge or two of flow fire; the wheels *a, a, a, a*, may be clothed with any number of cases, so that the star-wheel consist of the same: the illuminating port-fires, which must be placed very near each other on the frames, must be so managed as to burn as long as the wheels, and lighted at the same time.

123. *The regulated illuminated Spiral Piece, with a projected Star-wheel illuminated.*

This piece is represented by fig. 2. and is thus made. Have a block made 8 inches diameter; in this block screw 6 iron spokes, which must serve for spindles for the spiral wheels: these wheels are made as usual, each 1½ foot diameter, and 3 feet in height: the spindles must be long enough to make the wheels 4 or 5 inches from one another: at the end of each spindle must be a

screw-nut, on which the wheels that hang downwards will run; and on the spindles which stand upwards must be a shoulder, for the blocks of the wheels to run on.

The projected star-wheel must turn on the same spindle on which the large block is fixed; this spindle must be long enough to allow the star-wheel to project a little before the spiral wheels: the exterior diameter of the star-wheel must be 3 feet 5. On this wheel fix 3 circles of iron wire, and on them port-fires; on the block place a transparent star, or a large 5-pointed brilliant star. The cafes on this wheel may burn 4 at once, as it will contain near twice the number of one of the spiral wheels: the cafes on the spiral wheels must be placed parallel to their fells, and burn two at a time.

125. *A Figure-piece illuminated with five-pointed Stars.*

Plate
cccxxxii.

The construction of this piece is very easy, as shewn by fig. 3. whose diameter from B to C is 8 feet, and from D to F 2 feet: the vertical wheel in the centre must be 1 foot diameter, and consist of 6 four-ounce cafes of different coloured charge, which cafes must burn double: on the frames fix 5 pointed brilliant or blue stars, rammed 4 inches with composition: let the space between each star be 8 inches; at each point fix a gerbe, or cafe of Chinese fire. When to be fired, let the gerbe, stars, and wheel, be lighted at the same time.

125. *The Star-wheel illuminated.*

This beautiful piece is shown by fig. 4. Its exterior fell is made of wood, 3 feet 6, or 4 feet diameter; within this fell, form with iron wire 3 circles, one less than the other, so that the diameter of the least may be about 10 inches: place the port-fires on these fells with their mouths inclining outwards, and the port-fires on the points of the star with their mouths projecting in front: let the exterior fell be clothed with 4 ounce cafes of grey charge: these cafes must burn 4 at a time, and be lighted at the same time as the illuminations.

126. *Pyramid of Flower-pots.*

Fig. 5 represents this curious piece, which must be made thus. Let the distance from A to B be 6 feet; and from one rail to the other, 2: on the bottom rail fix 5 paper mortars, each 3 $\frac{1}{4}$ inches diameter; these mortars load with serpents, crackers, stars, &c.

In the centre of each mortar fix a cafe of spur-fire: on the second rail fix 4 mortars, so as to stand exactly in the middle of the intervals of them on the bottom rail; on the third rail place 3 mortars; on the fourth, 2; and on the top of the posts, 1: the bottom rail must be 6 feet long: all the mortars must incline a little forwards, that they may easily discharge; and the spur-fires rammed exactly alike, that the mortars may all be fired at the same time. Having prepared your pyramid according to the preceding directions, carry pipes of communication from one spur-fire to the other.

127. *The illuminated Regulating Piece.*

Fig. 6. represents one half of this piece. A, A, A, A, are flat wooden spokes, each 5 feet long: at the end of each place a vertical wheel, 10 inches diameter, closed with 6 four-ounce cafes of brilliant fire: these cafes must burn but 1 at a time: on two of the spokes of each wheel place 2 port-fires, which must be lighted with the first cafe of the wheel; on each spoke A, A, &c. behind the wheels, place 6 cafes of the same size with those on the wheels: these cafes must be tied across the spokes with their mouths all one way,

and be made to take fire successively one after the other, so that they may assist the whole pieces to turn round.

The diameter of the large wheel must be 2 $\frac{1}{2}$ feet; and its fell made of wood, which must be fixed to the large spokes: on this wheel place 24 cafes of the same sort with those on the small wheels; these cafes must burn 4 at a time: in this wheel make 3 circles with iron wire, and on them place illuminating port-fires, as in the figure: the star-points on the large spokes may be made of thin ash hoops; the diameter of these points close to the centre-wheel must be 11 inches: on these points place port-fires, at 3 $\frac{1}{2}$ inches distance one from the other.

Fig. 7. represents the blocks of this piece. The diameters of these blocks, at A and B, must be 8 inches; and C and D, 4 $\frac{1}{2}$ inches: the length of each of these blocks must be 6 inches: at the small ends of these blocks fix an iron wheel 5 inches diameter, which wheels must have teeth, to turn the wheel E: this wheel is fixed on a small spindle screwed into the large spindle, which goes through the two blocks, and on which they run.

Supposing fig. 6. to be on the block A, in fig. 7. and to turn to the right, and another piece of the same construction on the block B, with its fires placed so as to turn it to the left; you will find them move very true and fast, by the help of the 3 iron wheels, which serve to regulate their motions, as well as to assist them in turning: let the iron circles in the front of the great wheels be of different diameters, so that when fired they may appear 6 circles. When this piece is fired, all the wheels and illuminations must be lighted at one time.

SECT. VI. *Aquatic Fire-works.*

WORKS that sport in the water are much esteemed by most admirers of fire-works, particularly water-rockets; and as they seem of a very extraordinary nature to those who are unacquainted with this art, they merit a particular explanation.

128. *Water-rockets,*

May be made from 4 oz. to 2 lb. If larger, they are too heavy; so that it will be difficult to make them keep above water without a cork float, which must be tied to the neck of the cafe; but the rockets will not dive so well with as without floats.

Cafes for these are made in the same manner and proportion as sky-rockets, only a little thicker of paper. When you fill those which are drove solid, put in first 1 ladleful of slow fire, then 2 of the proper charge, and on that 1 or 2 ladles of sinking charge, then the proper charge, then the sinking charge again, and so on, till you have filled the cafe within 3 diameters; then drive on the composition 1 ladleful of clay; through which make a small hole to the charge; then fill the cafe, within $\frac{1}{2}$ a diameter, with corn-powder, on which turn down 2 or 3 rounds of the cafe in the inside; then pinch and tie the end very tight; having filled your rockets (according to the above directions), dip their ends in melted rosin or sealing wax, or else secure them well with grease. When you fire those rockets, throw in 6 or 8 at a time; but, if you would have them all sink, or swim, at the same time,

Aquatic
Fire-works

time, you must drive them with an equal quantity of composition, and fire them altogether.

129. *To make Pipes of Communication, which may be used under Water.*

Pipes for this purpose must be a little thicker of paper than those for land. Having rolled a sufficient number of pipes, and kept them till dry, wash them over with drying oil, and set them to dry; but when you oil them, leave about $1\frac{1}{2}$ inch at each end dry, for joints: if they were oiled all over, when you come to join them, the paste would not stick where the paper is greasy: after the leaders are joined, and the paste dry, oil the joints. These pipes will lie many hours under water, without receiving any damage.

130. *Horizontal Wheels for the Water.*

First get a large wooden bowl without a handle; then have an octagon wheel made of a flat board 18 inches diameter, so that the length of each side will be near 7 inches: in all the sides cut a groove for the cafes to lie in. This wheel being made, nail it on the top of the bowl; then take 4-eight oz. cafes, filled with a proper charge, each about 6 inches in length. Now, to clothe the wheel with these cafes, get some whitish-brown paper, and cut it into slips 4 or 5 inches broad and 7 or 8 long: these slips being pasted all over on one side, take one of the cafes, and roll one of the slips of paper about $1\frac{1}{4}$ inch on its end, so that there will remain about $2\frac{1}{2}$ inches of the paper hollow from the end of the cafe: this cafe tie on one of the sides of the wheel, near the corners of which must be holes bored, through which you put the packthread to tie the cafes: having tied on the first cafe at the neck and end, put a little meal-powder in the hollow paper; then paste a slip of paper on the end of another cafe, the head of which put into the hollow paper on the first, allowing a sufficient distance from the tail of one to the head of the other for the pasted paper to bend without tearing: the second cafe tie on as you did the first: and so on with the rest, except the last, which must be closed at the end, unless it is to communicate to any thing on the top of the wheel, such as fire-pumps or brilliant fires, fixed in holes cut in the wheel, and fired by the last or second cafe, as the fancy directs: 6, 8, or any number, may be placed on the top of the wheel, provided they be not too heavy for the bowl.

Before you tie on the cafes, cut the upper part of all their ends, except the last, a little shelving, that the fire from one may play over the other, without being obstructed by the cafe. Wheel-cafes have no clay drove in their ends, nor pinched, but are always left open, only the last, or those which are not to lead fire, which must be well secured.

131. *Water Mines.*

For these mines you must have a bowl with a wheel on it, made in the same manner as the water-wheel; only in its middle there must be a hole, of the same diameter you design to have the mine. These mines are tin pots, with strong bottoms, and a little more than 2 diameters in length: your mine must be fixed in the hole in the wheel, with its bottom resting on the bowl; then loaded with serpents, crackers, stars, small water-rockets, &c. in the same manner as pots of aigrettes; but in their centre fix a cafe of Chinese fire, or a small

gerbe, which must be lighted at the beginning of the last cafe on the wheel. These wheels are to be clothed as usual.

132. *Fire-globes for the Water.*

Bowls for water-globes must be very large, and the wheels on them of a decagon form: on each side of which nail a piece of wood 4 inches long; and on the outside of each piece cut a groove, wide enough to receive about $\frac{1}{4}$ of the thickness of a 4-oz. cafe: these pieces of wood must be nailed in the middle of each face of the wheel, and fixed in an oblique direction, so that the fire from the cafes may incline upwards: the wheel being thus prepared, tie in each groove a 4-oz. cafe, filled with a grey charge; then carry a leader from the tail of one cafe to the mouth of the other.

Globes for these wheels are made of 2 tin hoops, with their edges outwards, fixed one within the other, at right angles. The diameter of these hoops must be somewhat less than that of the wheel. Having made a globe, drive in the centre of a wheel an iron spindle, which must stand perpendicular, and its length 4 or 6 inches more than the diameter of the globe.

This spindle serves for an axis, on which the globe is fixed, which, when done, must stand 4 or 6 inches from the wheel: round one side of each hoop must be foldered little bits of tin, $2\frac{1}{2}$ inches distance from each other; which pieces must be 2 inches in length each, and only fastened at one end, the other ends being left loose, to turn round the small port-fires, and hold them on: these port-fires must be made of such a length as will last out the cafes on the wheel. You are to observe, that there need not be any port-fires at the bottom of the globe within 4 inches of the spindle; for, if there were, they would have no effect, but only burn the wheel: all the port-fires must be placed perpendicular from the centre of the globe, with their mouths outwards; and must all be clothed with leaders, so as all to take fire with the second cafe of the wheel; which cafes must burn two at a time, one opposite the other. When two cafes of a wheel begin together, two will end together: therefore the two opposite end cafes must have their ends pinched and secured from fire. The method of firing such wheels is, by carrying a leader from the mouth of one of the first cafes to that of the other; which leader being burnt through the middle, will give fire to both at the same time.

133. *Odoriferous Water Balloons.*

These balloons are made in the same manner as air-balloons, but very thin of paper, and in diameter $1\frac{1}{4}$ inch, with a vent of $\frac{1}{2}$ inch diameter. The shells being made, and quite dry, fill them with any of the following compositions, which must be rammed in tight: these balloons must be fired at the vent, and put into a bowl of water. Odoriferous works are generally fired in rooms.

Composition I. Saltpetre 2 oz. flour of sulphur 1 oz. camphor $\frac{1}{2}$ oz. yellow amber $\frac{1}{2}$ oz. charcoal-dust $\frac{1}{4}$ oz. flour of benjamin or assa odorata $\frac{1}{2}$ oz. all powdered very fine and well mixed.

II. Saltpetre 12 oz. meal-powder 3 oz. frankincense 1 oz. myrrh $\frac{1}{2}$ oz. camphor $\frac{1}{2}$ oz. charcoal 3 oz. all moistened with the oil of spike.

III. Saltpetre 2 oz. sulphur $\frac{1}{2}$ oz. antimony $\frac{1}{2}$ oz. amber $\frac{1}{2}$ oz. cedar raspings $\frac{1}{4}$ oz. all mixed with the oil of roses and a few drops of bergamot.

Aquatic
Fire-works

Aquatic
Fire-worksAquatic
Fire-works

IV. Saltpetre 4 oz. sulphur 1 oz. saw-dust of juniper $\frac{1}{2}$ oz. saw-dust of cypress 1 oz. camphor $\frac{1}{4}$ oz. myrrh 2 drachms, dried rosemary $\frac{1}{4}$ oz. cortex elaterii $\frac{1}{2}$ oz. all moistened a little with the oil of roses.

N. B. Water rockets may be made with any of the above compositions, with a little alteration, to make them weaker or stronger, according to the size of the cases.

134. Water Balloons.

Having made some thin paper shells, of what diameter you please, fill some with the composition for water balloons, and some after this manner: Having made the vent of the shells pretty large, fill them almost full with water rockets, marrons, squibs, &c. Then put in some blowing powder, sufficient to burst the shells; and afterwards fix in the vent a water rocket, long enough to reach the bottom of the shell, and its neck to project a little out of the vent; this rocket must be open at the end, to fire the powder in the shell, which will burst the shell, and disperse the small rockets, &c. in the water. When you have well secured the large rocket in the vent of the shell, take a cork float with a hole in its middle, which fit over the head of the rocket, and fasten it to the shell: this float must be large enough to keep the balloon above water.

135. Water Squibs

Are generally made of 1-oz. serpent cases seven or eight inches long, filled two-thirds with charge, and the remainder bounced. The common method of firing them is this: Take a water-wheel, with a tin mortar in its centre, which load with squibs after the usual method; but the powder in the mortar must be no more than will just throw the squibs out easily into the water: you may place the cases on the wheel either obliquely or horizontally; and on the top of the wheel, round the mortar, fix six cases of brilliant fire perpendicular to the wheel: these cases must be fired at the beginning of the last case of the wheel, and the mortar at the conclusion of the same.

136. A Sea-fight with small Ships, and to prepare a Fire-ship for it.

Having procured four or five small ships, of two or three feet in length, (or as many as you design to fight), make a number of small reports, which are to serve for guns. Of these range as many as you please on each side of the upper decks; then at the head and stern of each ship fix a two-ounce case, eight inches long, filled with a slow port-fire receipt; but take care to place it in such a manner that the fire may fall in the water, and not burn the rigging: in these cases bore holes at unequal distances from one another, but make as many in each case as half the number of reports, so that one case may fire the guns on one side, and the other those on the opposite. The method of firing the guns is, by carrying a leader from the holes in the cases to the reports on the decks; you must make these leaders very small, and be careful in calculating the burning of the slow-fire in the regulating cases, that more than two guns be not fired at a time. When you would have a broadside given, let a leader be carried to a cracker, placed on the outside of the ship; which cracker must be tied loose, or the reports will be too slow: in all the ships put artificial guns at the port-holes.

Having filled and bored holes in two port-fires for regulating the guns in one ship, make all the rest ex-

actly the same; then, when you begin the engagement, light one ship first, and set it a sailing, and so on with the rest, sending them out singly, which will make them fire regularly, at different times, without confusion; for the time between the firing of each gun will be equal to that of lighting the slow fires.

The fire-ship may be of any size; and need not be very good, for it is always lost in the action. To prepare a ship for this purpose, make a port-fire equal in size with those in the other ships, and place it at the stern; in every port place a large port-fire, filled with a very strong composition, and painted in imitation of a gun, and let them all be fired at once by a leader from the slow fire, within two or three diameters of its bottom: a'l along both sides, on the top of the upper deck, lay star-composition about half an inch thick and one broad, which must be wetted with thin size, then primed with meal-powder, and secured from fire by pasting paper over it; in the place where you lay this composition, drive some little tacks with flat heads, to hold it fast to the deck: this must be fired just after the sham guns, and when burning will show a flame all round the ship: at the head take up the decks, and put in a tin mortar loaded with crackers, which mortar must be fired by a pipe from the end of the slow fire; the firing of this mortar will sink the ship, and make a pretty conclusion. The regulating port-fire of this ship must be lighted at the same time with the first fighting ship.

Having prepared all the ships for fighting, we shall next proceed with the management of them when on the water. At one end of the pond, just under the surface of the water, fix two running blocks, at what distance you choose the ships should fight; and at the other end of the pond, opposite to each of these blocks, under the water, fix a double block; then on the land, by each of the double blocks, place two small windlasses; round one of them turn one end of a small cord, and the other end put through one of the blocks; then carry it through the single one at the opposite end of the pond, and bring it back through the double block again, and round the other windlass: to this cord, near the double block, tie as many small strings as half the number of the ships, at what distance you think proper; but these strings must not be more than two feet each: make fast the loose end of each to a ship, just under her bow-sprit; but if tied to the keel, or too near the water, it will overset the ship. Half the ships being thus prepared, near the other double block fix two more windlasses, to which fasten a cord, and to it tie the other half of the ships as before: when you fire the ships, pull in the cord with one of the windlasses, to get all the ships together; and when you have set fire to the first, turn that windlass which draws them out, and so on with the rest, till they are all out in the middle of the pond; then, by turning the other windlass, you will draw them back again; by which method you may make them change sides, and tack about backwards and forwards at pleasure. For the fire-ship, fix the blocks and windlasses between the others; so that when she sails out, she will be between the other ships: you must not let this ship advance till the guns at her ports take fire.

137. To fire Sky-rockets under Water,

You must have stands made as usual, only the rails must

Aquatic
Fire-works

must be placed flat instead of edgewise, and have holes in them for the rocket-sticks to go through; for if they were hung upon hooks, the motion of the water would throw them off: the stands being made, if the pond is deep enough, sink them at the sides so deep, that, when the rockets are in, their heads may just appear above the surface of the water; to the mouth of each rocket fix a leader, which put through the hole with the stick; then a little above the water must be a board, supported by the stand, and placed along one side of the rockets; then the ends of the leaders are turned up through holes made in this board, exactly opposite the rockets. By this means you may fire them singly or all at once. Rockets may be fired by this method in the middle of a pond, by a Neptune, a swan, a water-wheel, or any thing else you choose.

138. *To represent Neptune in his Chariot.*

To do this to perfection, you must have a Neptune (made of wood, or basket work) as big as life, fixed on a float large enough to bear his weight; on which must be two horses heads and necks, so as to seem swimming, as shown by fig. 11. For the wheels of the chariot, there must be two vertical wheels of black fire, and on Neptune's head a horizontal wheel of brilliant fire, with all its cafes, to play upwards. When this wheel is made, cover it with paper or paste-board, cut and painted like Neptune's coronet; then let the trident be made without prongs, but instead of them, fix three cafes of a weak grey charge, and on each horse's head put an eight ounce cafe of brilliant fire, and on the mouth of each fix a short cafe, of the same diameter, filled with the white-flame receipt, enough to last out all the cafes on the wheels: these short cafes must be open at bottom, that they may light the brilliant fires; for the horses eyes put small port-fires, and in each nostril put a small cafe filled half with grey charge, and the rest with port-fire composition.

If Neptune is to give fire to any building on the water; at his first setting out, the wheels of the chariot, and that on his head, with the white flames on the horses heads, and the port-fires in their eyes and nostrils, must all be lighted at once; then from the bottom of the white flames carry a leader to the trident. As Neptune is to advance by the help of a block and cord, you must manage it so as not to let him turn about, till the brilliant fires on the horses and the trident begin; for it is by the fire from the horses (which plays almost upright) that the building, or work, is lighted; which must be thus prepared. From the mouth of the cafe which is to be first fired, hang some loose quick-match to receive the fire from the horses. When Neptune is only to be shown by himself, without setting fire to any other works, let the white flames on the horses be very short, and not last longer than

one cafe of each wheel, and let two cafes of each wheel burn at a time.

139. *Swans and Ducks in Water.*

If you would have the swans or ducks discharge rockets into the water, they must be made hollow, and of paper, and filled with small water rockets, with some blowing powder to throw them out: but if this is not done, they may be made of wood, which will last many times. Having made and painted some swans, fix them on floats: then in the places where their eyes should be, bore holes two inches deep, inclining downwards, and wide enough to receive a small port-fire; the port-fire cafes for this purpose must be made of brass, two inches long, and filled with a slow bright charge. In the middle of one of these cafes make a little hole; then put the port-fire in the eye-hole of the swan, leaving about half an inch to project out; and in the other eye put another port-fire, with a hole made in it: then in the neck of the swan, within two inches of one of the eyes, bore a hole slantwise, to meet that in the port-fire; in this hole put a leader, and carry it to a water-rocket, that must be fixed under the tail with its mouth upwards. On the top of the head place two 1-oz. cafes, four inches long each, drove with brilliant fire; one of these cafes must incline forwards, and the other backwards: these must be lighted at the same time as the water-rocket; to do which, bore a hole between them in the top of the swan's head, down to the hole in the port-fire, to which carry a leader: if the swan is filled with rockets, they must be fired by a pipe from the end of the water-rocket under the tail. When you set the swan a swimming, light the two eyes.

140. *Water Fire-fountains.*

To make a fire-fountain, you must first have a float made of wood, three feet diameter; then in the middle fix a round perpendicular post, four feet high, and two inches diameter; round this post fix three circular wheels made of thin wood, without any spokes. The largest of these wheels must be placed within two or three inches of the float, and must be nearly of the same diameter. The second wheel must be 2 feet 2 inches diameter, and fixed at two feet distance from the first. The third wheel must be 1 foot 4 inches diameter, and fixed within six inches of the top of the post: the wheels being fixed, take 18 four or eight oz. cafes of brilliant fire, and place them round the first wheel with their mouths outwards, and inclining downwards; on the second wheel place 13 cafes of the same, and in the same manner as those on the first; on the third, place 8 more of these cafes, in the same manner as before, and on the top of the post fix a gerbe; then clothe all the cafes with leaders, so that both they and the gerbe may take fire at the same time. Before you fire this work, try it in the water to see if the float is properly made, so as to keep the fountain upright.

chius
||
Pyrus.

serve the pace of the Pyrrhic foot.—Others derive the name from Pyrrhus the son of Achilles, who instituted this exercise at the obsequies of his father.—Aristotle says, that it was Achilles himself who invented it.

The Romans also called it *ludus Trojanus*, “the Trojan game; and Aulus Gellius, *decursus*.—It is doubtless this exercise that we see represented on medals by two cavaliers in front running with lances, and the word *decursio* in the exergum.

PYRRHICHIUS, in the Greek and Latin poetry, a foot consisting of two syllables, both short;—as, *Deus*.—Among the ancients this foot is also called *periambus*; by others *hegemonia*.

PYRRHO, a Greek philosopher, born at Elis in Peloponnesus, flourished about 300 B. C. He was the disciple of Anaxarchus, whom he accompanied as far as India, where he conversed with the Brachmans and Gymnosophists. He had made painting his profession before he devoted himself to the study of philosophy. He established a sect whose fundamental principle was, That there is nothing true or false, right or wrong, honest or dishonest, just or unjust; or that there is no standard of any thing beyond law or custom, and that uncertainty and doubt belong to every thing. From this continual seeking after truth and never finding it, the sect obtained the name of *Sceptics* or *Pyrrhonians* from the founder, who is said to have acted upon his own principles, and to have carried his scepticism to such a ridiculous extreme, that his friends were obliged to accompany him wherever he went, that he might not be run over by carriages, or fall down precipices. If this was true, it was not without reason that he was ranked among those whose intellects were disturbed by intense study. But it is treated by a modern writer as a mere calumny invented by the dogmatists; and we are strongly inclined to be of his opinion, (see *SCPTICS*.) Pyrrho died about the 90th year of his age, when his memory was honoured with a statue at Athens, and a monument erected to him in his own country.

PYRRHUS, the name of two kings of EPIRUS. See that article.

PYRUS, the PEAR-TREE: A genus of the pentagynia order, belonging to the icosandria class of plants; and in the natural method ranking under the 36th order, *Pomaceæ*. The calyx is quinquefid; there are five petals; the fruit is an apple, inferior, quinquelocular, and polyspermous. To this genus Linnæus has joined the apple and quince; but, on account of the remarkable difference between the fruits, the last is treated under the article CYDONIA. The other species are,

1. The communis, or common pear-tree, rises with an upright large trunk, branching 30 or 40 feet high, in some widely around, in others more erectly, and forming a conical head; oval, lanceolated, serrated leaves, and corymbose clusters of white flowers from the sides of the branches, succeeded by large fruit extended at the base. Under this species are comprehended almost endless varieties, all bearing the above description. They bear their flowers and fruit upon spurs, arising from the sides of the branches from two or three years old and upwards; the same branches and spurs continuing fruitful for a great number of

years. The different varieties furnish fruit for use from the beginning of July till the months of May and June, next year; which, according to their times of ripening may be divided into three classes, summer-pears, autumn-pears, and winter-pears. The summer-pears ripen in different sorts from the beginning of July until the middle or end of September, and are generally fit to eat from the tree, or at least do not keep a week or two before they rot. The autumn pears come to their perfection in October, November, and December; some ripening nearly on the tree in October and the beginning of November, others requiring to lie some time in the fruitery, while some will keep two months; but all the winter-pears, though they attain their full growth on the tree by the end of October and in November, yet they do not acquire perfection for eating till from the end of November to April and May. Those of each class have different properties; some being melting, others breaking, some mealy, and some hard and austere, fit only for kitchen uses. As many of the finest sorts were first obtained from France, they are still continued in most catalogues by French names.

2. The malus, or common apple-tree, grows 20 or 30 feet high, having oval serrated leaves, and sessile umbels of whitish red flowers, succeeded by large, roundish, and oblong fruit, concave at the base. The apple is composed of four distinct parts, viz. the pill, the parenchyma, the branchery, and the core. The pill or skin is only a dilatation of the outermost skin or rind of the bark of the branch on which it grew. The parenchyma or pulp, as tender and delicious as it is found, is only a dilatation, or, as Dr Grew calls it, a *swellth* or superbiency of the inner part of the bark of the branch. This appears not only from the visible continuation of the bark from the one through the pedicle or stalk to the other, but also from the structure common to both. The branchery or vessels are only ramifications of the woody part of the branch, sent throughout all the parts of the parenchyma, the greater branches being made to communicate with each other by inoculations of the less. The apple core is originally from the pith of the branch; the sap of which finding room enough in the parenchyma through which to diffuse itself, quits the pith, which by this means hardens into core. The varieties of this species are amazingly great with respect to the differences of the fruit. The botanists contend, that the wilding, or crab-apple of the woods and hedges, is the original kind, and from the seeds of which the cultivated apple was first obtained. The varieties of this last no doubt are multiplied to some hundreds in different places, having been all first accidentally obtained from the seed or kernels of the fruit, and the approved sorts continued and increased by grafting upon crabs or any kind of apple-stocks: but although the number of varieties is very considerable, there are not above 40 or 50 sorts retained in the nurserymens catalogue. These varieties arrive at full growth in successive order from July to the end of October, improve in perfection after being gathered; and several of the winter kinds, in particular, keep good for many months, even till the arrival of apples next summer.

Among these various kinds of apples some are used for the desert, some for the kitchen, and some for cyder.

der-making. Those used for the desert are the following, placed as they successively ripen after one another: The white juncating, the margaret apple, the summer pearmain, the summer queening, the embroidered apple, the golden rennet, the summer white calville, the summer red calville, the silver pippen, the aromatic pippen, *la reinette grise*, *la haute bonte*, the royal ruffling, Wheeler's ruffet, Sharp's ruffet, the spine apple, the golden pippen, the nonpareil, the *l'asi* or *pomme d'asi*. Those for the kitchen use, in the order of their ripening, are these: The codling, the summer marygold, the summer red pearmain, the Holland pippen, the Kentish pippen, the courpendu, Loan's pearmain, the French renet, the French pippen, the royal ruffet, the monstrous rennet, the winter pearmain, the *pomme violette*, Spencer's pippen, the stone pippen, and the oaken pippen. Those most esteemed for cyder are, the Devonshire royal wilding, the redstreak apple, the whitfour, the Herefordshire under-leaf, and the John apple, or *deux annes*, everlasting hanger, and geunet moyle.

The juice of apples is a menstruum for iron. A solution of iron in the juice of the apples called *golden rennets*, evaporated to a thick consistence, proves an elegant chalybeate, which keeps well.

The best method of preserving apples for winter use, is to let them hang upon the trees until there is danger of frost, to gather them in dry weather, and then to lay them in large heaps to sweat for a month or six weeks. They ought then to be carefully looked over, all which have the least appearance of decay taken out, the sound fruit wiped dry, and packed up in large oil jars, which have been thoroughly scalded and dry, and then stopped close to exclude the air. If this plan is duly observed, the fruit will keep a long time sound, and their flesh remain plump; whereas, when exposed to the air, their skins will shrivel, and their pulp soften.

3. The coronaria, or sweet-scented crab of Virginia, grows 12 or 15 feet high, having angular, serrated leaves, pedunculated umbels of whitish-red, sweet-scented flowers, succeeded by small round crabs, remarkably four and austere. There is one variety, called the *ever-green Virginian crab tree*.

Culture. All the varieties of the pear-tree are hardy, and will succeed in any common soil of a garden or orchard. They are propagated by grafting and budding upon any kind of pear-stocks; also occasionally upon quince-stocks, and sometimes upon white-thorn stocks; but pear-stocks are greatly preferable to all others for general use.—All kinds of apples are propagated in the same manner; using apple-stocks instead of pear-stocks. They will succeed in any common soil of a garden or orchard, and in any free situation except in a low and very moist soil, in which they are apt to canker, and very soon go off. In a friable loam they are generally very successful.

PYTHAGORAS, a celebrated philosopher of antiquity, respecting the time and place of whose birth the learned are much divided. Eratosthenes asserts, that in the 48th Olympiad*, when he was very young, he was a victor at the Olympic games. Hence Dr Bentley† determines the date of his birth to be the 4th year of the 43d Olympiad; whilst Lloyd‡, who denies that the Olympic victor was the same person with the philosopher, places it about the 3d year of the 48th Olympiad. Mr Dodwell§ differs from both, and wishes

to fix the birth of Pythagoras in the 4th year of the 52d Olympiad. Of the arguments of these learned writers, Le Clerc has given a summary in the *Bibliothèque Choise*, tom. x. p. 81. &c. and from a review of the whole, it would appear that he was not born earlier than the 4th year of the 43d Olympiad, nor later than the 4th year of the 52d; but in what particular year of that period his birth took place, cannot with any degree of certainty be ascertained. It is generally believed that he was born in the island of Samos, and that he flourished about 500 years before Christ, in the time of Tarquin the last king of Rome*. His father Mnesarchus, who is thought by some to have been a lapidary, and by others a merchant of Tyre, appears to have been a man of some distinction, and to have bestowed upon his son the best education.

Jamblicus† relates a number of wonderful stories respecting Pythagoras's descent from Jupiter, his birth, and early life; and represents him even in his youth as a prodigy of wisdom and manly seriousness. But most of these idle tales confute themselves, afford nothing of importance to be depended upon, and only prove the credulity, carelessness, and prejudice of their author. Of his childhood and early education we know nothing, except that he was first instructed in his own country by Creophilus, and afterwards in Scyry by Pherecydes (see PHERECYDES). According to the custom of the times he was made acquainted with poetry and music; eloquence and astronomy became his private studies, and in gymnastic exercises he often bore the palm for strength and dexterity. He first distinguished himself in Greece at the Olympic games, where, beside gaining the prize, he is said to have excited the highest admiration by the elegance and dignity of his person, and the brilliancy of his understanding.

Soon after his appearance at these games Pythagoras commenced his travels in quest of knowledge. He first visited Egypt, where, through the interest of Polycrates tyrant of Samos, he obtained the patronage of Amasis king of Egypt, by whose influence, combined with his own assiduity, patience, and perseverance, he at length gained the confidence of the priests; from whom he learned their sacred mysteries, theology, and the whole system of symbolical learning. In Egypt, too, he became acquainted with geometry and the true solar system; and, before he left that country, made himself master of all the learning for which it was so famed among the nations of antiquity.

He afterwards visited Persia and Chaldea, where from the Magi he learnt divination, the interpreting of dreams, and astronomy. He is likewise said to have travelled into India, to have conversed with the Gymnosophists, and to have acquired from them a knowledge of the philosophy and literature of the east; and such was his ardour in the pursuit of science, that in quest of it, we are told by Cicero*, he crossed many seas, and travelled on foot through many barbarous nations.

After Pythagoras had spent many years in gathering information on every subject, especially respecting the nature of the gods, the rites of religion, and the immortality of the human soul, he returned to his native island, and attempted to make his knowledge useful by instituting a school for the instruction of his countrymen. Failing of success in this laudable undertaking, he

Pythago-
ras.

repaired to Delos, where he pretended to receive moral dogmas from the priests of Apollo. He also visited Crete, where he was initiated into the most sacred mysteries of Greece. He went likewise to Sparta and Elis, and again assisted at the Olympic games; where in the public assembly he was saluted with the title of *sophist* or *wise man*, which he declined for one more humble. See PHILOLOGY, n° 1. and PHILOSOPHY n° 1.

He returned to Samos enriched with mythological learning and mysterious rites, and again instituted a school. His mysterious symbols and oracular precepts made this attempt more successful than the former had been; but meeting with some opposition, or being detected in some pious frauds, he suddenly left Samos, retired to Magna Grecia, and settled at Crotona.

Here he founded the Italic sect (see PHILOSOPHY n° 20.); and his mental and personal accomplishments, the fame of his distant travels, and his Olympic crown, soon procured him numerous pupils. His bold and manly eloquence and graceful delivery attracted the most dissolute, and produced a remarkable change in the morals of the people of Crotona. His influence was increased by the regularity of his own example, and its conformity to his precepts. He punctually attended the temples of the gods, and paid his devotions at an early hour; he lived upon the purest and most innocent food, clothed himself like the priests of Egypt, and by his continual purifications and regular offerings appeared to be superior in sanctity to the rest of mankind. He endeavoured to assuage the passions of his scholars with verses and numbers, and made a practice of composing his own mind every morning, by playing on his harp, and singing along with it the pæans of Thales. To avoid the temptations of ease and the seductions of idleness, bodily exercises also made a considerable part of his discipline.

At Crotona he had a public school for the general benefit of the people, in which he taught them their duty, praising virtue and condemning vice; and particularly instructing them in the duties of social life. Besides this, he had a college in his own house, which he denominated *κοινωβιον*, in which there were two classes of students, viz. *ἐξωτερικοι*, who were also called *auscultantes* and *εσωτερικοι*. The former of these were probationers, and were kept under a long examen. A silence of five years was imposed upon them; which Apuleius thinks was intended to teach them modesty and attention; but Clemens Alexandrinus thinks it was for the purpose of abstracting their minds from sensible objects, and inuring them to the pure contemplation of the Deity. The latter class of scholars were called *genuini*, *perfecti*, *mathematici*, and, by way of eminence, *Pythagoreans*. They alone were admitted to the knowledge of the arcana and depths of Pythagoric discipline, and were taught the use of ciphers and hieroglyphic writings.

Clemens observes, that these orders corresponded very exactly to those among the Hebrews: for in the schools of the prophets there were two classes, viz. the sons of the prophets, who were the scholars, and the doctors or masters, who were also called *perfecti*; and among the Levites, the novices or tyros, who had their quinquennial exercises, by way of preparation. Lastly, even among the profelytes there were two or-

ders; *exoterici*, or profelytes of the gate; and *intrinseci* or *perfecti*, profelytes of the covenant. He adds, it is highly probable, that Pythagoras himself had been a profelyte of the gate, if not of the covenant. Gale endeavours to prove that Pythagoras borrowed his philosophy from that of the Jews; to this end producing the authorities of many of the fathers and ancient authors, and even pointing out the tracks and footsteps of Moses in several parts of Pythagoras's doctrine. But we believe the learned author was misled by the Christian Platonists.

The authority of Pythagoras among his pupils was so great, that it was even deemed a crime to dispute his word; and their arguments were considered as infallibly convincing, if they could enforce them by adding, that "the master said so;" an expression which afterwards became proverbial in *jurare in verba magistri*. This influence over his school was soon extended to the world, and even his pupils themselves divided the applause and approbation of the people with their master; and the rulers and legislators of all the principal towns of Greece, Sicily, and Italy, boasted of being the disciples of Pythagoras. To give more weight to his exhortations, as some writers mention, Pythagoras retired into a subterraneous cave, where his mother sent him intelligence of every thing which happened during his absence. After a certain number of months he again re-appeared on the earth with a grim and ghastly countenance, and declared in the assembly of the people that he was returned from hell. From similar exaggerations it has been asserted that he appeared at the Olympic games with a golden thigh, and that he could write in letters of blood whatever he pleased on a looking-glass; and that by setting it opposite to the moon, when full, all the characters which were on the glass became legible on the moon's disc. They also relate, that by some magical words he tamed a bear, stopped the flight of an eagle, and appeared on the same day and at the same instant in the cities of Crotona and Metapontum, &c.

At length his singular doctrines, and perhaps his strenuously asserting the rights of the people against their tyrannical governors, excited a spirit of jealousy, and raised a powerful party against him; which soon became so outrageous as to oblige him to fly for his life. His friends fled to Rhegium; and he himself, after being refused protection by the Locrians, fled to Metapontum, where he was obliged to take refuge in the temple of the muses, and where it is said he died of hunger about 497 years before Christ. Respecting the time, place, and manner of his death, however, there are various opinions, and many think it uncertain when, where, or in what manner, he ended his days. After his death his followers paid the same respect to him as was paid to the immortal gods; they erected statues in honour of him, converted his house at Crotona into a temple of Ceres, appealed to him as a deity, and swore by his name.

Pythagoras married Theano of Crotona, or, according to others, of Crete, by whom he had two sons, Telauges and Mnearchus, who, after his death, took care of his school. He is said also to have had a daughter called *Damo*.

Whether he left any writings behind him is disputed. It seems probable, however, that he left none, and that such

Pythago-
ras.

Pythagoras.

such as went under his name were written by some of his followers. The *golden verses* which Hierocles illustrated with a commentary, have been ascribed to Epicharmus or Empedocles, and contain a brief summary of his popular doctrines. From this circumstance, and from the mysterious secrecy with which he taught, our information concerning his doctrine and philosophy is very uncertain, and cannot always be depended on.

The purpose of philosophy, according to the system of Pythagoras, is to free the mind from incumbrances, and to raise it to the contemplation of immutable truth and the knowledge of divine and spiritual objects. To bring the mind to this state of perfection is a work of some difficulty, and requires a variety of intermediate steps. Mathematical science was with him the first step to wisdom, because it inures the mind to contemplation, and takes a middle course between corporeal and incorporeal beings. The whole science he divided into two parts, *numbers* and *magnitude*; and each of these he subdivided into two others, the former into *arithmetic* and *music*, and the latter into *magnitude at rest* and *in motion*; the former of which comprehends *geometry*, and the latter *astronomy*. Arithmetic he considered as the noblest science, and an acquaintance with numbers as the highest good. He considered numbers as the principles of every thing; and divided them into scientific and intelligible. Scientific number is the production of the powers involved in unity, and its return to the same; number is not infinite, but is the source of that infinite divisibility into equal parts which is the property of all bodies. Intelligible numbers are those which existed in the divine mind before all things. They are the model or archetype of the world, and the cause of the essence of beings. Of the Monad, Duad, Triad, Tetrad, and Decad, various explanations have been given by various authors; but nothing certain or important is known of them. In all probability, numbers were used by Pythagoras as symbolical representations of the first principles and forms of nature, and especially of those eternal and immutable essences which Plato denominated ideas; and in this case the monad was the simple root from which he conceived numbers to proceed, and as such, analogous to the simple essence of deity; from whence, according to his system, the various properties of nature proceed.

Music followed numbers, and was useful in raising the mind above the dominion of the passions. Pythagoras considered it as a science to be reduced to mathematical principles and proportions, and is said to have discovered the musical chords from the circumstance of several men successively striking with hammers a piece of heated iron upon an anvil. This story Dr Burney* discredits; but allows, from the uniform testimony of writers ancient and modern, that he invented the *harmonical canon* or monochord, (see MONOCHORD.) The music of the spheres, of which every one has heard, was a most fanciful doctrine of Pythagoras. It was produced, he imagined, by the planets striking on the ether through which in their motion they passed; and he considered their musical proportions as exact, and their harmony perfect.

Pythagoras, as we have already seen, learned geometry in Egypt; but by investigating many new theorems, and by digesting its principles, he reduced it to a more regular science. A geometrical point, which he defines

to be a monad, or unity with position, he says corresponds to unity in arithmetic, a line to two, a superficies to three, and a solid to four. He discovered several of the propositions of Euclid; and on discovering the 47th of book 1st, he is said to have offered a hecatomb to the gods; but as he was averse to animal sacrifices, this assertion is surely false. His great progress in astronomical science has been mentioned elsewhere. See ASTRONOMY, n° 11, 22; and PHILOSOPHY, n° 15, 16.

Wisdom, according to Pythagoras, is conversant with those objects which are naturally immutable, eternal, and incorruptible; and its end is to assimilate the human mind to the divine, and to qualify us to join the assembly of the gods. Active and moral philosophy prescribes rules and precepts for the conduct of life, and leads us to the practice of public and private virtue.— On these heads many of his precepts were excellent, and some of them were whimsical and useless. Theoretical philosophy treats of nature and its origin, and is, according to Pythagoras, the highest object of study. It included all the profound mysteries which he taught, of which but little is now known. God he considers as the universal mind, diffused through all things, and the self-moving principle of all things (*αὐτοματισμός τῶν πάντων*), and of whom every human soul is a portion*. It is very probable, that he conceived of the Deity as a subtle fire, eternal, active, and intelligent; which is not inconsistent with the idea of incorporeality, as the ancients understood that term. This Deity was primarily combined with the chaotic mass of passive matter, but he had the power of separating himself, and since the separation he has remained distinct. The learned Cudworth contends, that Pythagoras maintained a trinity of hypostases in the divine nature, similar to the Platonic triad (see PLATONISM). We cannot say that his arguments appear to have much force; but we think the conclusion which he wishes to establish extremely probable, as Plato certainly drew his doctrine from some of the countries which Pythagoras had visited before him.

Subordinate to the Deity there were in the Pythagorean creed three orders of intelligences, gods, demons, and heroes, of different degrees of excellence and dignity. These, together with the human soul, were considered as emanations from the Deity, the particles of subtle ether assuming a grosser clothing the farther they receded from the fountain. Hierocles defines a hero to be a rational mind united with a luminous body. God himself was represented under the notion of monad, and the subordinate intelligences as numbers derived from and included in unity. Man is considered as consisting of an elementary nature and a divine or rational soul. His soul, a self-moving principle, is composed of two parts; the rational, seated in the brain; and the irrational, including the passions, in the heart. In both these respects he participates with the brutes, whom the temperament of their body, &c. allows not to act rationally. The sensitive soul perishes; the other assumes an ethereal vehicle, and passes to the regions of the dead, till sent back to the earth to inhabit some other body, brutal or human. See METEMPSYCHOSIS. It was unquestionably this notion which led Pythagoras and his followers to deny themselves the use of flesh, and to be so peculiarly merciful to animals of every description. Some authors, however, say, that flesh and beans, the use of which he also forbade, were prohibited,

Pythagoras.

* Cicero de Senect.
§ 21.

* History of Music, vol. i. p. 441.

Pythagoras, because he supposed them to have been produced from the same putrified matter, from which, at the creation of the world, man was formed.

Of the symbols of Pythagoras little is known. They have been religiously concealed; and though they have awakened much curiosity, and occasioned many ingenious conjectures, they still appear to us dark and trifling. As a specimen we give the following: "Adore the sound of the whispering wind. Stir not the fire with a sword. Turn aside from an edged tool. Pass not over a balance. Setting out on a journey, turn not back, for the furies will return with you. Breed nothing that hath crooked talons. Receive not a swallow into your house. Look not in a mirror by the light of a candle. At a sacrifice pair not your nails. Eat not the heart or brain. Taste not that which hath fallen from the table. Break not bread. Sleep not at noon. When it thunders touch the earth. Pluck not a crown. Roast not that which has been boiled. Sail not on the ground. Plant not a palm. Breed a cock, but do not sacrifice it, for it is sacred to the sun and moon. Plant mallows in thy garden, but eat them not. Abstain from beans."

The following precepts are more important: "Discourse not of Pythagorean doctrines without light. Above all things govern your tongue. Engrave not the image of God in a ring. Quit not your station without the command of your general. Remember that the paths of virtue and of vice resemble the letter Y. To this symbol Perſius refers †, when he says,

*Et tibi quæ Samios diduxit litera ramos,
Surgentem dextro monstravit limite collem.*

There has the Samian Y's instructive make
Pointed the road thy doubtful foot should take;
There warn'd thy raw and yet unpractis'd youth,
To tread the rising right-hand path of truth.

The scantiness and uncertainty of our information respecting Pythagoras, renders a regular and complete account of his life and doctrines impossible. A modern author ‡ of profound erudition pronounces him to have been *unquestionably* the wisest man that ever lived, if his masters the Egyptian priests must not be excepted. This is saying a great deal too much; but that he was one of the most distinguished philosophers of antiquity, or, as Cicero expresses it, *vir præstanti*

ſapientia, appears very evident; and his moral character has never been impeached. The mysterious air which he threw over his doctrines, and the apparent inanity of some of his symbols, have indeed subjected him to the charge of imposture, and perhaps the charge is not wholly groundless: but when we consider the age in which he lived, and the nature of the people with whom he had to deal, who would in all probability have resisted more open innovations, even this will not appear so blameable as at first sight we are apt to think it; and it is worthy of notice, that the worst stories of this kind have come down to us in a very questionable shape, and with much probability appear to be false.

PYTHAGOREANS, a sect of ancient philosophers, so called from being the followers of Pythagoras. See the preceding article.

PYTHIA, the priestess of Apollo at Delphi, by whom he delivered oracles. She was so called from Pythius, a name of that god, which is said to have been given him on account of his victory over the serpent Python.

The Pythia was at first required to be a young girl, but in later times she was a woman of 50 years of age. The first and most famous Pythia was Phenemonœ. Oracles were at first delivered by her in hexameter verse. All the Pythias were to be pure virgins, and all of them delivered their oracles with great enthusiasm and violent agitations. See ORACLE and DELPHI.

PYTHIAN GAMES, in Grecian antiquity, sports instituted near Delphos in honour of Apollo, on account of his slaying the serpent Python. See APOLLO.—These games, at their first institution, were celebrated only once in nine years; but afterwards every fifth year, from the number of the Parnassian nymphs who came to congratulate Apollo, and to make him presents on his victory. The victor was crowned with garlands.

PYTHON, in fabulous history, a monstrous serpent, produced by the earth after Deucalion's deluge. Juno being exasperated at Latona, who was beloved by Jupiter, commanded this serpent to destroy her; but flying from the pursuit of the monster, she escaped to Delos, where she was delivered of Diana and Apollo; the latter of whom at length destroyed Python with his arrows, in memory of which victory the Pythian games were instituted. See APOLLO.

Q.

Q, or q, the 16th letter and 12th consonant of our alphabet; but is not to be found either in the Greek, old Latin, or Saxon alphabets; and indeed some would entirely exclude it, pretending that k ought to be used wherever this occurs. However, as it is formed in the voice in a different manner, it is undoubtedly a distinct letter: for, in expressing this sound, the cheeks are contracted, and the lips, particularly the

under, one, are put into a canular form, for the passage of the breath.

The q is never sounded alone, but in conjunction with u, as in *quality*, *question*, *quite*, *quote*, &c. and never ends any English word.

As a numeral, Q stands for 500; and with a dash over it, thus Q̄, for 500,000.

Used as an abbreviature, signifies *quantity*, or *quantum*.

Pythagoras.

Pythagoreans
Python.

Quab
||
Quadrant.

tum. Thus, among physicians, *q. pl.* is *quantum placet*, i. e. "as much as you please" of a thing; and *q. s.* is *quantum sufficit*, i. e. "as much as is necessary." Q. E. D. among mathematicians, is *quod erat demonstrandum*, i. e. "which was to be demonstrated;" and Q. E. F. is *quod erat faciendum*, i. e. "which was to be done." Q. D. among grammarians, is *quæd dictum*, i. e. "as if it were said;" or, "as who should say." In the notes of the ancients, Q stands for *Quintus*, or *Quinius*; Q. B. V. for *quod bene vertit*; Q. S. S. S. for *quæ supra scripta sunt*; Q. M. for *Quintus Mutius*, or *quomodo*; Quint. for *Quintilius*; and Quæst. for *quæstor*.

QUAB, in ichthyology, the name of a Russian fish, which is said to be at first a tadpole, then a frog, and at last a fish. Dr Mounsey, who made many inquiries concerning these pretended changes, considers them all as fabulous. He had opportunity of seeing the fish itself, and found that they spawned like other fishes, and grew in size, without any appearances to justify the report. He adds, that they delight in very clear water, in rivers with sandy or stony bottoms, and are never found in standing lakes, or in rivers passing through marshy or mossy grounds, where frogs choose most to be.

QUABES, are a free people of Africa, inhabiting the southern banks of the river Sestos, and between that and Sierra Leona. They are under the protection of the emperor of Manow.

QUACHA, or QUAGGA. See EQUUS, n° 5.

QUACHILTO, in ornithology, is the name of a very beautiful Brazilian bird, called also *yacazinli*, and *porphyrio Americanus*. It is of a fine blackish purple colour, variegated with white; its beak is white while young, but becomes red as it grows older, and has a naked space at its basis, resembling in some sort the coot; its legs are of a yellowish green; it lives about the waters, and feeds on fish, yet is a very well tasted bird. It imitates the crowing of a common cock, and makes its music early in the morning.

QUACK, among physicians, the same with empiric. See the article EMPIRIC.

QUADI, (Tacitus); a people of Germany, situated to the south-east of the mountains of Bohemia, on the banks of the Danube, and extending as far as the river Marus, or March, running by Moravia, which country they occupied.

QUADRAGESIMA, a denomination given to lent, from its consisting of 40 days. See LENT.

QUADRANGLE, in geometry, the same with a quadrilateral figure, or one consisting of four sides and four angles.

QUADRANS, the quarter or fourth part of any thing, particularly the *as*, or pound.

QUADRANS, in English money, the fourth part of a penny. Before the reign of Edward I. the smallest coin was a *sterling*, or penny, marked with a cross; by the guidance of which a penny might be cut into halves for a halfpenny, or into quarters or four parts for farthings; till, to avoid the fraud of unequal cuttings, that king coined halfpence and farthings in distinct round pieces.

QUADRANT, in geometry, the arch of a circle, containing 90°, or the fourth part of the entire periphery.

Sometimes also the space or area, included between this arch and two radii drawn from the centre to each extremity thereof, is called a *quadrant*, or, more properly, a *quadrantal space*, as being a quarter of an entire circle.

QUADRANT, also denotes a mathematical instrument of great use in astronomy and navigation, for taking the altitudes of the sun and stars, as also for taking angles in surveying, &c.

This instrument is variously contrived, and furnished with different apparatus, according to the various uses it is intended for; but they all have this in common, that they consist of a quarter of a circle, whose limb is divided into 90°. Some have a plummet suspended from the centre, and are furnished with sights to look through.

The principal and most useful quadrants are the common surveying quadrant, astronomical quadrant, Adams's quadrant, Cole's quadrant, Gunter's quadrant, Hadley's quadrant, horodistical quadrant, Sutton's or Collins's quadrant, and the sinical quadrant, &c. Of each of which in order.

1. The common surveying quadrant, is made of brass, wood, or any other solid substance; the limb of which is divided into 90°, and each of these farther divided into as many equal parts as the space will allow, either diagonally or otherwise. On one of the semidiameters are fitted two moveable sights; and to the centre is sometimes also fixed a label, or moveable index, bearing two other sights; but in lieu of these last sights there is sometimes fitted a telescope: also from the centre there is hung a thread with a plummet; and on the under side or face of the instrument is fitted a ball and socket, by means of which it may be put into any position. The general use of it is for taking angles in a vertical plane, comprehended under right lines going from the centre of the instrument, one of which is horizontal, and the other is directed to some visible point. But besides the parts already described, there is frequently added on the face, near the centre, a kind of compartment, called the *quadrat*, or *geometrical square*. See QUADRAT.

This quadrant may be used in different situations: for observing heights or depths, its plane must be disposed perpendicularly to the horizon; but to take horizontal distances, its plane is disposed parallel thereto. Again, heights and distances may be taken two ways, viz. by means of the fixed sights and plummet, or by the label: As to which, and the manner of measuring angles, see GEOMETRY, p. 674, &c.

2. The astronomical quadrant is a large one, usually made of brass, or wooden bars faced with iron plates; having its limbs nicely divided, either diagonally or otherwise, into degrees, minutes and seconds; and furnished with two telescopes, one fixed on the side of the quadrant, and the other moveable about the centre, by means of the screw. There are also dented wheels, which serve to direct the instrument to any object or phenomenon.—The use of this curious instrument, in taking observations of the sun, planets, and fixed stars, is obvious; for being turned horizontally upon its axis, by means of the telescope, till the object is seen through the moveable telescope, then the degrees, &c. cut by the index give the altitude required. See ASTRONOMY, p. 587, &c.

Quadrant.
Plate
ccccxxvii.

3. Cole's quadrant is a very useful instrument invented by Mr Benjamin Cole. It consists of 6 parts, *viz.* the staff AB (fig. 1.); the quadrantal arch DE; three vanes A, B, C; and the vernier FG. The staff is a bar of wood about two feet long, an inch and a quarter broad, and of a sufficient thickness to prevent it from bending or warping. The quadrantal arch is also of wood; and is divided into degrees, and third-parts of a degree, to a radius of about nine inches; to its extremities are fitted two radii, which meet in the centre of the quadrant by a pin, round which it easily moves. The sight-vane A is a thin piece of brass, almost two inches in height and one broad, placed perpendicularly on the end of the staff A, by the help of two screws passing through its foot. Through the middle of this vane is drilled a small hole, through which the coincidence or meeting of the horizon and solar spot is to be viewed. The horizon vane B is about an inch broad, and two inches and a half high, having a slit cut thro' it of near an inch long and a quarter of an inch broad; this vane is fixed in the centre pin of the instrument, in a perpendicular position, by the help of two screws passing through its foot, whereby its position with respect to the sight-vane is always the same, their angles of inclination being equal to 45 degrees. The shade-vane C is composed of two brass plates. The one, which serves as an arm, is about four inches and a half long, and three quarters of an inch broad, being pinned at one end to the upper limb of the quadrant by a screw, about which it has a small motion; the other end lies in the arch, and the lower edge of the arm is directed to the middle of the centre-pin; the other plate, which is properly the vane, is about two inches long, being fixed perpendicularly to the other plate, at about half an inch distance from that end next the arch; this vane may be used either by its shade or by the solar spot cast by a convex lens placed therein. And, because the wood-work is often apt to warp or twist, therefore this vane may be rectified by the help of the screw, so that the warping of the instrument may occasion no error in the observation, which is performed in the following manner: Set the line G on the vernier against a degree on the upper limb of the quadrant, and turn the screw on the backside of the limb forward or backward, till the hole in the sight-vane, the centre of the glass, and the sunk spot in the horizon-vane, lie in a right line.

To find the sun's altitude by this instrument: Turn your back to the sun, holding the instrument by the staff with your right hand, so that it be in a vertical plane passing through the sun; apply your eye to the sight-vane, looking through that and the horizon-vane till you see the horizon; with the left hand slide the quadrantal arch upwards, until the solar spot or shade, cast by the shade-vane, fall directly on the spot or slit in the horizon-vane; then will that part of the quadrantal arch, which is raised above G or S (according as the observation respected either the solar spot or shade) show the altitude of the sun at that time. But if the meridian altitude be required, the observation must be continued; and as the sun approaches the meridian, the sea will appear through the horizon-vane, and then is the observation finished; and the degrees and minutes, counted as before, will give the sun's meridian

altitude: or the degrees counted from the lower limb upwards will give the zenith-distance. Quadrant.

4. Adams's quadrant differs only from Cole's quadrant in having an horizontal vane, with the upper part of the limb lengthened; so that the glass, which casts the solar spot on the horizon-vane, is at the same distance from the horizon-vane as the sight-vane at the end of the index.

5. Gunter's quadrant, so called from its inventor Edmund Gunter, besides the usual apparatus of other quadrants, has a stereographical projection of the sphere on the plane of the equinoctial. It has also a kalendar of the months, next to the divisions of the limb.

Use of Gunter's quadrant. 1. To find the sun's meridian altitude for any given day, or the day of the month for any given meridian altitude. Lay the thread to the day of the month in the scale next the limb; and the degree it cuts in the limb is the sun's meridian altitude. Thus the thread, being laid on the 15th of May, cuts $59^{\circ} 30'$, the altitude sought; and, contrarily, the thread, being set to the meridian altitude, shows the day of the month. 2. To find the hour of the day. Having put the bead, which slides on the thread, to the sun's place in the ecliptic, observe the sun's altitude by the quadrant; then, if the thread be laid over the same in the limb, the bead will fall upon the hour required. Thus suppose on the 10th of April, the sun being then in the beginning of Taurus, I observe the sun's altitude by the quadrant to be 36° ; I place the bead to the beginning of Taurus in the ecliptic, and lay the thread over 36° of the limb; and find the bead to fall on the hour-line marked 3 and 9; accordingly the hour is either 9 in the morning or 3 in the afternoon. Again, laying the bead on the hour given, having first rectified or put it to the sun's place, the degree cut by the thread on the limb gives the altitude. Note, the bead may be rectified otherwise, by bringing the thread to the day of the month, and the bead to the hour-line of 12. 3. To find the sun's declination from his place given, and contrariwise. Set the bead to the sun's place in the ecliptic, move the thread to the line of declination, and the bead will cut the degree of declination required. Contrarily, the bead being adjusted to a given declination, and the thread moved to the ecliptic, the bead will cut the sun's place. 4. The sun's place being given, to find his right ascension, or contrarily. Lay the thread on the sun's place in the ecliptic, and the degree it cuts on the limb is the right ascension sought. Contrarily, laying the thread on the right ascension, it cuts the sun's place in the ecliptic. 5. The sun's altitude being given, to find his azimuth, and contrariwise. Rectify the bead for the time, as in the second article, and observe the sun's altitude: bring the thread to the complement of that altitude; thus the bead will give the azimuth sought, among the azimuth lines. 6. To find the hour of the night from some of the five stars laid down on the quadrant. (1.) Put the bead to the star you would observe, and find how many hours it is off the meridian, by article 2. (2.) Then, from the right ascension of the star, subtract the sun's right ascension converted into hours, and mark the difference; which difference, added to the observed hour of the star from the meridian,

diar.

Quadrant. dian, shows how many hours the sun is gone from the meridian, which is the hour of the night. Suppose on the 15th of May the sun is in the 4th degree of Gemini, I set the bead to Arcturus; and, observing his altitude, find him to be in the west about 50° high, and the bead to fall on the hour-line of 2 in the afternoon; then will the hour be 11 hours 50 minutes past noon, or 10 minutes short of midnight: for 62° , the sun's right ascension, converted into time, makes 4 hours 8 minutes; which, subtracted from 13 hours 58 minutes, the right ascension of Arcturus, the remainder will be 9 hours 50 minutes; which added to 2 hours, the observed distance of Arcturus from the meridian, shows the hour of the night to be 11 hours 50 minutes.

The mural quadrant has already been described under the article ASTRONOMY, n^o 497. It is a most important instrument, and has of late been much improved by Mr Ramsden, who has distinguished himself by the accuracy of his divisions, and by the manner in which he finishes the planes by working them in a vertical position. He places the plumb-line behind the instrument, that there may be no necessity for removing it when we take an observation near the zenith. His manner of suspending the glass, and that of throwing light on the object-glass and on the divisions at the same time, are new, and improvements that deserve to be noticed.—Those of eight feet, which he has made for the observatories of Padua and Vilna, have been examined by Dr Maskelyne; and the greatest error does not exceed two seconds and a half. That of the same size for the observatory of Milan is in a very advanced state. The mural quadrant, of six feet, at Blenheim, is a most admirable instrument. It is fixed to four pillars, which turn on two pivots, so that it may be put to the north and to the south in one minute. It was for this instrument Mr Ramsden invented a method of rectifying the arc of 90 degrees, on which an able astronomer had started some difficulties; but by means of an horizontal line and a plumb-line, forming a kind of cross, without touching the circle, he showed him that there was not an error of a single second in the 90 degrees; and that the difference was occasioned by a mural quadrant of Bird, in which the arc of 90 degrees was too great by several seconds, and which had never been rectified by so nice a method as that of Mr Ramsden.

But the quadrant is not the instrument which stands highest in Mr Ramsden's opinion; it is the complete circle: and he has demonstrated to M. de la Lande, that the former must be laid aside, if we would arrive at the utmost exactness of which an observation is capable. His principle reasons are: 1. The least variation in the centre is perceived by the two diametrically opposite points. 2. The circle being worked on the turn, the surface is always of the greatest accuracy, which it is impossible to obtain in the quadrant. 3. We may always have two measures of the same arc, which will serve for the verification of each other. 4. The first point of the division may be verified every day with the utmost facility. 5. The dilatation of the metal is uniform, and cannot produce any error. 6. This instrument is a meridian glass at the same time. 7. It also becomes a moveable azimuth circle by adding an hori-

zontal circle beneath its axis, and then gives the refractions independent of the mensuration of time.

6. Hadley's quadrant is an instrument of vast utility both in navigation and practical astronomy. It derives its name from Mr Hadley, who first published an account of it, though the first thought originated with the celebrated Dr Hooke, and was completed by Sir Isaac Newton (see ASTRONOMY, n^o 32. and also n^o 17. and 22.) The utility of this quadrant arises from the accuracy and precision with which it enables us to determine the latitude and longitude; and to it is navigation much indebted for the very great and rapid advances it has made of late years. It is easy to manage, and of extensive use, requiring no peculiar steadiness of hand, nor any such fixed basis as is necessary to other astronomical instruments. It is used as an instrument for taking angles in maritime surveying, and with equal facility at the mast head as upon the deck, by which its sphere of observation is much extended; for supposing many islands to be visible from the mast head, and only one from deck, no useful observation can be made by any other instrument. But by this, angles may be taken at the mast head from the one visible object with great exactness; and further, taking angles from heights, as hills, or a ship mast's head, is almost the only way of exactly describing the figure and extent of shoals.

It has been objected to the use of this instrument for surveying, that it does not measure the horizontal angles, by which alone a plan can be laid down. This objection, however true in theory, may be reduced in practice by a little caution; and Mr Adams has given very good directions for doing so.

Notwithstanding, however, the manifest superiority of this instrument over those that were in use at the time of its publication, it was many years before the sailors could be persuaded to adopt it, and lay aside their imperfect and inaccurate instruments; so great is the difficulty to remove prejudice, and emancipate the mind from the slavery of opinion. No instrument has undergone, since the original invention, more changes than the quadrant of Hadley; of the various alterations, many had no better foundation than the caprice of the makers, who by these attempts have often rendered the instrument more complicated in construction, and more difficult in use, than it was in its original state.

It is an essential property of this instrument, derived from the laws of reflection, that half degrees on the arch answer to whole ones in the angles measured: hence an octant, or the eighth part of a circle, or 45 degrees on the arch, serves to measure 90 degrees; and sextants will measure an angular distance of 120 degrees, tho' the arch of the instrument is no more than 60 degrees. It is from this property that foreigners term that instrument an *octant*, which we usually call a *quadrant*, and which in effect it is. This property reduces indeed considerably the bulk of the instrument: but at the same time it calls for the utmost accuracy in the divisions, as every error on the arch is doubled in the observation.

Another essential, and indeed an invaluable, property of this instrument, whereby it is rendered peculiarly advantageous in marine observations, is, that it is not liable

Quadrant.

Quadrant.

to be disturbed by the ship's motion; for provided the mariner can see distinctly the two objects in the field of his instrument, no motion nor vacillation of the ship will injure his observation.

Thirdly, the errors to which it is liable are easily discovered and readily rectified, while the application and use of it is facile and plain.

To find whether the two surfaces of any one of the reflecting glasses be parallel, apply your eye at one end of it, and observe the image of some object reflected very obliquely from it; if that image appears single, and well-defined about the edges, it is a proof that the surfaces are parallel: on the contrary, if the edge of the reflected images appear misted, as if it threw a shadow from it, or separated like two edges, it is a proof that the two surfaces of the glass are inclined to each other: if the image in the speculum, particularly if that image be the sun, be viewed through a small telescope, the examination will be more perfect.

To find whether the surface of a reflecting glass be plane. Choose two distant objects, nearly on a level with each other; hold the instrument in an horizontal position, view the left hand object directly through the transparent part of the horizon-glass, and move the index till the reflected image of the other is seen below it in the silvered part: make the two images unite just at the line of separation, then turn the instrument round slowly on its own plane, so as to make the united images move along the line of separation of the horizon-glass. If the images continue united without receding from each other, or varying their respective position, the reflecting surface is a good plane.

To find if the two surfaces of a red or darkening glass are parallel and perfectly plane. This must be done by means of the sun when it is near the meridian, in the following manner: hold the sextant vertically, and direct the sight to some object in the horizon, or between you and the sky, under the sun; turn down the red glass and move the index till the reflected image of the sun is in contact with the object seen directly: fix then the index, and turn the red glass round in its square frame; view the sun's image and object immediately, and if the sun's image is neither raised nor depressed, but continues in contact with the object below, as before, then the surfaces of the darkening glass are true.

For a more particular description of Hadley's quadrant, and the mode of using it, see NAVIGATION, Book II. Chap. I.

This instrument has undergone several improvements since its first invention, and among these improvers must be ranked Mr Ramsden. He found that the essential parts of the quadrant had not a sufficient degree of solidity; the friction at the centre was too great, and in general the alidada might be moved several minutes without any change in the position of the mirror; the divisions were commonly very inaccurate, and Mr Ramsden found that Abbé de la Caille did not exceed the truth in estimating at five minutes the error to which an observer was liable in taking the distance between the moon and a star; an error capable of producing a mistake of 50 leagues in the longitude. On this account Mr Ramsden changed the principle of construc-

tion of the centre, and made the instrument in such a manner as never to give an error of more than half a minute; and he has now brought them to such a degree of perfection as to warrant it not more than six seconds in a quadrant of fifteen inches. Since the time of having improved them, Mr Ramsden has constructed an immense number; and in several which have been carried to the East Indies and America, the deficiency has been found no greater at their return than it had been determined by examinations before their being taken out. Mr Ramsden has made them from 15 inches to an inch and a half, in the latter of which the minutes are easily distinguishable; but he prefers for general use those of 10 inches, as being more easily handled than the greater, and at the same time capable of equal accuracy. See SEXTANT.

A great improvement was also made in the construction of this quadrant by Mr Peter Dollond, famous for his invention of achromatic telescopes. The glasses of the quadrants should be perfect planes, and have their surfaces perfectly parallel to one another. By a practice of several years, Mr Dollond found out methods of grinding them of this form to great exactness; but the advantage which should have arisen from the goodness of the glasses was often defeated by the index-glass being bent by the frame which contains it. To prevent this, Mr Dollond contrived the frame so that the glass lies on three points, and the part that presses on the front of the glass has also three points opposite to the former. These points are made to confine the glass by three screws at the back, acting directly opposite to the points between which the glass is placed. The principal improvements, however, are in the methods of adjusting the glasses, particularly for the back-observation. The method formerly practised for adjusting that part of the instrument by means of the opposite horizons at sea, was attended with so many difficulties that it was scarce ever used: for so little dependence could be placed on the observations taken this way, that the best Hadley's sextants made for the purpose of observing the distances of the moon from the sun or fixed stars have been always made without the horizon-glass, for the back observation; for want of which, many valuable observations of the sun and moon have been lost, when their distance exceeded 120 degrees. To make the adjustment of the back-observation easy and exact, he applied an index to the back horizon-glass, by which it may be moved in a parallel position to the index-glass, in order to give it the two adjustments in the same manner as the fore-horizon-glass is adjusted. Then, by moving the index to which the back-horizon-glass is fixed exactly 90 degrees (which is known by the divisions made for that purpose), the glass will thereby be set at right angles to the index-glass, and will be properly adjusted for use; and the observations may be made with the same accuracy by this as by the fore-observation. To adjust the horizon-glasses in the perpendicular position to the plane of the instrument, he contrived to move each of them by a single screw, which goes through the frame of the quadrant, and is turned by means of a milled head at the back; which may be done by the observer while he is looking at the object. To these improvements also

Quadrant.

he

Quadrant. he added a method invented by Mr Maskelyne, of placing darkening-glasses behind the horizon-glasses. These, which serve for darkening the object seen by direct vision, in adjusting the instrument by the sun or moon, he placed in such a manner as to be turned behind the fore horizon-glass, or behind the back horizon-glass: there are three of these glasses of different degrees of darkness.

We have been the more particular in our description and use of Hadley's quadrant, as it is undoubtedly the best hitherto invented.

Plate
ccccxxvii.

7. Horodistical quadrant, a pretty commodious instrument, so called from its use in telling the hour of the day.—Its construction is this: From the centre of the quadrant, C, fig. 3. whose limb AB is divided into 90° , describe seven concentric circles at intervals at pleasure; and to these add the signs of the zodiac, in the order represented in the figure. Then applying a ruler to the centre C and the limb AB, mark upon the several parallels the degrees corresponding to the altitude of the sun when therein, for the given hours; connect the points belonging to the same hour with a curve line, to which add the number of the hour. To the radius CA fit a couple of sights, and to the centre of the quadrant C tie a thread with a plummet, and upon the thread a bead to slide. If now the thread be brought to the parallel wherein the sun is, and the quadrant directed to the sun, till a visual ray pass through the sights, the bead will show the hour; for the plummet, in this situation, cuts all the parallels in the degrees corresponding to the sun's altitude. Since the bead is in the parallel which the sun describes, and through the degrees of altitude to which the sun is elevated every hour there pass hour-lines, the bead must show the present hour. Some represent the hour-lines by arches of circles, or even by straight lines, and that without any sensible error.

8. Sutton's or Collins's quadrant (fig. 4.) is a stereographic projection of one quarter of the sphere between the tropics, upon the plane of the ecliptic, the eye being in its north-pole: it is fitted to the latitude of London. The lines running from the right hand to the left are parallels of altitude; and those crossing them are azimuths. The lesser of the two circles, bounding the projection, is one fourth of the tropic of Capricorn; the greater is one fourth of that of Cancer. The two ecliptics are drawn from a point on the left edge of the quadrant, with the characters of the signs upon them; and the two horizons are drawn from the same point. The limb is divided both into degrees and time; and, by having the sun's altitude, the hour of the day may be found here to a minute. The quadrantal arches next the centre contain the calendar of months; and under them, in another arch, is the sun's declination. On the projection are placed several of the most noted fixed stars between the tropics; and the next below the projection is the quadrant and line of shadows.—To find the time of the sun's rising or setting, his amplitude, his azimuth, hour of the day, &c. by this quadrant: lay the thread over the day and the month, and bring the bead to the proper ecliptic, either of summer or winter, according to the season, which is called *rectifying*; then, moving the thread, bring the bead to the horizon, in which case the thread will cut the limb in the time of the sun's rising or set-

VOL. XV.

Quadrant. ting before or after six; and at the same time the bead will cut the horizon in the degrees of the sun's amplitude.—Again, observing the sun's altitude with the quadrant, and supposing it found 45° on the fifth of May, lay the thread over the fifth of May, bring the bead to the summer ecliptic, and carry it to the parallel of altitude 45° ; in which case the thread will cut the limb at $55^{\circ} 15'$, and the hour will be seen among the hour-lines to be either 41' past nine in the morning, or 19' past two in the afternoon.—Lastly, the bead among the azimuths shows the sun's distance from the south $50^{\circ} 41'$. But note, that if the sun's altitude be less than what it is at six o'clock, the operation must be performed among those parallels above the upper horizon; the bead being rectified to the winter ecliptic.

9. Sinical quadrant (fig. 5.) consists of several concentric quadrantal arches, divided into eight equal parts by radii, with parallel right lines crossing each other at right angles. Now any one of the arches, as BC, may represent a quadrant of any great circle of the sphere, but is chiefly used for the horizon or meridian. If then BC be taken for a quadrant of the horizon, either of the sides, as AB, may represent the meridian; and the other side, AC, will represent a parallel, or line of east and west: and all the other lines, parallel to AB, will be also meridians; and all those parallel to AC, east and west lines, or parallels.—Again, the eight spaces into which the arches are divided by the radii, represent the eight points of the compass in a quarter of the horizon; each containing $11^{\circ} 15'$. The arch BC is likewise divided into 90° , and each degree subdivided into 12', diagonal-wise. To the centre is fixed a thread, which, being laid over any degree of the quadrant, serves to divide the horizon.

If the sinical quadrant be taken for a fourth part of the meridian, one side thereof, AB, may be taken for the common radius of the meridian and equator; and then the other, AC, will be half the axis of the world. The degree of the circumference, BC, will represent degrees of latitude; and the parallels to the side AB, assumed from every point of latitude to the axis AC, will be radii of the parallels of latitude, as likewise the sine complement of those latitudes.

Suppose, then, it be required to find the degrees of longitude contained in 83 of the lesser leagues in the parallel of 48° ; lay the thread over 48° of latitude on the circumference, and count thence the 83 leagues on AB, beginning at A; this will terminate in H, allowing every small interval four leagues. Then tracing out the parallel HE, from the point H to the thread; the part AE of the thread shows that 125 greater or equinoctial leagues make $6^{\circ} 15'$; and therefore that the 83 lesser leagues AH, which make the difference of longitude of the course, and are equal to the radius of the parallel HE, make $6^{\circ} 15'$ of the said parallel.

If the ship sails an oblique course, such course, besides the north and south greater leagues, gives lesser leagues easterly and westerly, to be reduced to degrees of longitude of the equator. But these leagues being made neither on the parallel of departure, nor on that of arrival, but in all the intermediate ones, we must find a mean proportional parallel between them. To find this, we have on the instrument a scale of cross latitudes. Suppose then it were required to find a

4 Z

mean

Quadrant
||
Quadrat.

mean parallel between the parallels of 40° and 60° ; with your compasses take the middle between the 40th and 60th degree on this scale: the middle point will terminate against the 51st degree, which is the mean parallel required.

The principal use of the finical quadrant is to form triangles upon, similar to those made by a ship's way with the meridians and parallels; the sides of which triangles are measured by the equal intervals between the concentric quadrants and the lines N and S, E and W: and every fifth line and arch is made deeper than the rest. Now, suppose a ship to have sailed 150 leagues north-east, one fourth north, which is the third point, and makes an angle of $33^{\circ} 44'$ with the north part of the meridian: here are given the course and distance sailed, by which a triangle may be formed on the instrument similar to that made by the ship's course; and hence the unknown parts of the triangle may be found. Thus, supposing the centre A to represent the place of departure; count, by means of the concentric circles along the point the ship sailed on, viz. AD, 150 leagues: then in the triangle AED, similar to that of the ship's course, find AE=difference of latitude, and DE=difference of longitude, which must be reduced according to the parallel of latitude come to.

10. Gunner's quadrant (fig. 6.), sometimes called *gunner's square*, is that used for elevating and pointing cannon, mortars, &c. and consists of two branches either of brass or wood, between which is a quadrantal arch divided into 90 degrees, beginning from the shorter branch, and furnished with a thread and plummet, as represented in the figure.—The use of the gunner's quadrant is extremely easy; for if the longest branch be placed in the mouth of the piece, and it be elevated till the plummet cut the degree necessary to hit a proposed object, the thing is done. Sometimes on one of the surfaces of the long branch are noted the division of diameters and weights of iron bullets, as also the bores of pieces.

QUADRANT of Altitude, is an appendage of the artificial globe, consisting of a lamina, or slip of brass, the length of a quadrant of one of the great circles of the globe, and graduated. At the end, where the division terminates, is a nut rivetted on, and furnished with a screw, by means whereof the instrument is fitted on the meridian, and moveable round upon the rivet to all points of the horizon.—Its use is to serve as a scale in measuring of altitudes, amplitudes, azimuths, &c. See ASTRONOMY, n^o 379, &c.

QUADRANTAL, in antiquity, the name of a vessel in use among the Romans for the measuring of liquids. It was at first called *amphora*; and afterwards *quadrantal*, from its form, which was square every way like a die. Its capacity was 80 libræ, or pounds of water, which made 48 sextaries, two uræ, or eight congi.

QUADRAT, a mathematical instrument, called also a *Geometrical Square*, and *Line of Shadows*: it is frequently an additional member on the face of the common quadrant, as also on those of Gunter's and Sutton's quadrants. See GEOMETRY, p. 672. and Plate CCXVII. fig. 1—5.

QUADRAT, in printing, a piece of metal used to fill up the void spaces between words, &c. There are qua-

drats of different sizes; as m-quadrats, n-quadrats, &c. which are respectively of the dimensions of these letters, only lower, that they may not receive the ink.

QUADRATIC EQUATIONS, in algebra, those wherein the unknown quantity is of two dimensions, or raised to the second power. See ALGEBRA.

QUADRATRIX, in geometry, a mechanical line, by means whereof we can find right lines equal to the circumference of circles, or other curves, and their several parts.

QUADRATURE, in geometry, denotes the squaring, or reducing a figure to a square. Thus, the finding of a square, which shall contain just as much surface or area as a circle, an ellipsis, a triangle, &c. is the quadrature of a circle, ellipsis, &c. The quadrature, especially among the ancient mathematicians, was a great postulatam. The quadrature of rectilinear figures is easily found, for it is merely the finding their areas or surfaces i. e. their squares; for the squares of equal areas are easily found by only extracting the roots of the areas thus found. See GEOMETRY, Part II. chap. 3. The quadrature of curvilinear spaces is of more difficult investigation; and in this respect extremely little was done by the ancients, except the finding the quadrature of the parabola by Archimedes. In 1657, Sir Paul Neil, Lord Brouncker, and Sir Christopher Wren, geometrically demonstrated the equality of some curvilinear spaces to rectilinear spaces; and soon after the like was proved both at home and abroad of other curves, and it was afterwards brought under an analytical calculus; the first specimen of which was given to the public in 1688 by Mercator, in a demonstration of Lord Brouncker's quadrature of the hyperbola, by Dr Wallis's reduction of a fraction into an infinite series by division. Sir Isaac Newton, however, had before discovered a method of attaining the quantity of all quadruple curves analytically by his fluxions before 1668. It is disputed between Sir Christopher Wren and Mr Huygens which of them first discovered the quadrature of any determinate cycloidal space. Mr Leibnitz afterwards found that of another space; and in 1669 Bernoulli discovered the quadrature of an infinity of cycloidal spaces both segments and sectors, &c. See GEOMETRY, Part II. chap. 3. prop. 33.; and FLUXIONS, p. 314.

QUADRATURE, in astronomy, that aspect of the moon when she is 90° distant from the sun; or when she is in a middle point of her orbit, between the points of conjunction and opposition, namely, in the first and third quarters. See ASTRONOMY, n^o 320, &c.

QUADRATUS, in anatomy, a name given to several muscles on account of their square figure. See ANATOMY, *Table of the Muscles*.

QUADREL, in building, a kind of artificial stone, so called from its being perfectly square. The quadrels are made of a chalky earth, &c. and dried in the shade for two years. These were formerly in great request among the Italian architects.

QUADRIGA, in antiquity, a car or chariot drawn by four horses. On the reverses of medals, we frequently see the emperor or Victory in a quadriga, holding the reins of the horses; whence these coins are, among the curious, called *nummi quadrigati*, and *victoriatii*.

Quadratic
||
Quadriga.

QUA-

Quadri-
lateral,
Quadrille.

QUADRILATERAL, in geometry, a figure whose perimeter consists of four sides and four angles; whence it is also called a *quadrangular figure*.

QUADRILLE, a little troop or company of cavaliers, pompously dressed, and mounted for the performance of carousals, jousts, tournaments, runnings at the ring, and other gallant diversifements.

QUADRILLE, a game played by four persons, with 40 cards; which are the remains of a pack, after the four tens, nines, and eights are discarded; these are dealt three and three, and one round four, to the right hand player; and the trump is made by him that plays with or without calling, by naming spades, clubs, diamonds, or hearts, and the suit named is trumps. If the person who names the trump should mistake, and say spades instead of clubs, or if he name two suits, the first named is the trump.

In this game the order of the cards, according to their natural value, is as follows: of hearts and diamonds, *king, queen, knave, ace, deuce, three, four, five, six, seven*; in all 10; of spades and clubs, *king, queen, knave, seven, six, five, four, three, deuce*; in all 9. The reason why the ace of spades and ace of clubs are not mentioned, is, because they are always trumps, in whatever suit that is played. The ace of spades being always the first, and the ace of clubs the third trump, for the cards ranked according to their value when *trumps* stand in the following order.

Hearts and diamonds **SPADILL**, or the *ace of spades*; **MANILL**, the *seventh* of the two *red suits*; **BASTO**, the *ace of clubs*; **PONTO**, the *ace of hearts and diamonds*; *king, queen, knave, deuce, three, four, five, six*; in all 12. Spades and clubs, **SPADILL** the *ace of spades*, **MANILL** the *deuce of spades and clubs*, **BASTO** the *ace of clubs*; *king, queen, knave, seven, six, five, four, three*; in all 11. It is here to be observed, that the card which is *manill* and the second trump, is always the lowest in its suit when not trumps; and that the ace of hearts or diamonds, which when trump is above the king, is below the knave when not trump.

There are three matadores; *spadill*, *manill*, and *basto*; the privilege of which is, that when the player has no other trumps but them, and trumps are led, he is not obliged to play them, but may play what card he thinks proper, provided, however, that the trump led is of an inferior rank; but if *spadill* should be led, he that has *manill* or *basto* only, is obliged to play it; it is the same of *manill*, *basto*, with respect to the superior matadore always forcing the inferior. Though there are properly but three matadores, nevertheless, all those trumps which follow the three first without interruption, are likewise called matadores; but the three first only enjoy the privilege abovementioned.

Each person is to play as he judges most convenient for his own game. He is not to encourage his friend to play; but each person ought to know what to do when it is his turn to play. The stakes consist of seven equal mils or *contrats*, as they are sometimes called, comprising the ten counters and fives, which are given to each player. A mil is equal to ten fives, and each

fives to ten counters: the value of the fives is according to the players agreement, as also the number of tours, which are generally fixed at ten, and marked by turning the corners of a card.

If the cards should happen not to be dealt right, or that there should be two cards of the same sort, as two deuces of spades, for example, there must be a new deal; provided it is discovered before the cards are all played. The cards must likewise be dealt over again in case a card is turned in dealing, as it might be of prejudice to him who should have it; and of course if there should be several cards turned. There is no penalty for dealing wrong, he who does so must only deal again.

When each player has got his ten cards, he that is on the right hand of the dealer, after examining his game, and finding his hand fit to play, asks if they play; or if he has not a good hand, he passes, and so the second, third, and fourth. All the four may pass; but he that has *spadill*, after having shown or named it, is obliged to play by calling a king. Whether the deal is played in this manner, or that one of the players has asked leave, nobody choosing to play without calling, the eldest hand must begin the play, first naming his suit, and the king which he calls; he who wins the trick plays another card, and so of the rest till the game is finished. The tricks then are counted; and if the ombre, that is, he who stands the game, has, together with him who is the king called, six tricks, they have won and are paid the game, the consolation, and the matadores, if they have them, and divide what is upon the game, and the beasts if there are any. But if they make only five tricks, it is a remise, and they are beasted, what goes upon the game, paying to the other players the consolation and the matadores. If the tricks are equally divided betwixt them, they are likewise beasted; and if they make only four tricks between them, it is a remise; if they make less they lose *codill* (A), and in that case they pay to their adversaries what they should have received if they had won; that is, the game, the consolation, and the matadores, if they have them, and are beasted what is upon the game: they who win *codill*, divide the stakes. The beast, and every thing else that is paid, is paid equally betwixt the two losers; one half by him that calls, and the other half by him that is called, as well in case of *codill* as a remise; unless the ombre does not make three tricks, in which case he that is called is not only exempted from paying half the beast, but also the game, the consolation, and the matadores if there are any, which the ombre in that case pays alone; and as well in case of a *codill* as a remise. This is done in order to oblige players not to play games that are unreasonable. There is, nevertheless, one case in which if the ombre makes only one trick, he is not beasted alone, and that is, when not having a good hand he passes, and all the other players have passed likewise; he having *spadill* is obliged to play. Here it would be unjust to oblige him to make three or four tricks; in this case, therefore, he that is

4 Z 2

called

(A) *Codill* is when those who defend the pool make more tricks than they who stand the game; which is called *winning the codill*.

Quadrille. called pays one half of the losings. For which reason he that has spadill with a bad hand, should pass, that if he is afterwards obliged to play by calling a king (which is called *forced spadill*), he may not be beasted alone. He that has once passed cannot be admitted to play; and he that has asked leave cannot refuse to play, unless any one should offer to play without calling.

He that has four kings, may call a queen to one of his kings, except that which is trump. He that wants one or more kings, may call one of those kings; but in that case, he must make six tricks alone, and consequently he wins or loses alone. The king of that suit in which he plays cannot be called. No one should play out of his turn, although he is not beasted for so doing. If he who is not the eldest hand has the king called, and plays spadill, manill, or basto, or even the king called in order to show that he is the friend, having other kings that he fears the ombre should trump, he is not to be allowed to go for the vole; he is even beasted, if it appears to be done with that intent. It is not permitted to show a hand though codill may already be won; that it may be seen whether the ombre is beasted alone. If the ombre or his friend shows their cards before they have made six tricks, thinking that they have made them, and there appears a possibility of preventing their making them, the other players can oblige them to play their cards as they think proper.

A player need only name his suit when he plays, without calling a king. He who plays without calling must make six tricks alone to win; for all the other players are united against him, and they are to do what they can to prevent his winning. He who plays without calling, is admitted to play in preference to him who would play with calling; however, if he that has asked leave will play without calling, he has the preference of the other who would force him. These are the two methods of play without calling that are called forced.

As he who plays without calling does not divide the winnings with any person, he consequently, when he loses, pays all by himself; if he loses by remise he is beasted, and pays each of the other players the consolation, the *fans appeller* (which is commonly, but improperly, called the *fans prendre*), and the matadores if there are any; if he loses codill he is likewise beasted, and pays to each player what he would have received from each if he had won. They who win codill divide what there is; and if there are any counters remaining, they belong to him of the three who shall have spadill or the highest trump the next deal. It is the same with regard to him who calls one of his own kings, he wins alone or loses alone as in the other case, except the *fans appeller*, which he does not pay if he loses, or receive if he wins, although he plays alone.

If he plays *fans appeller*, though he may have a sure game, he is obliged to name his suit; which if he neglects to do, and shows his cards, and says, "I play *fans appeller*;" in that case either of the other players can oblige him to play in what suit he pleases, although he should not have one trump in that suit.

He who has asked leave is not permitted to play *fans appeller*, unless he is forced; in which case, as was

said before, he has the preference of the other that Quadrille. forces him.

A player is not obliged to trump when he has none of the suit led, nor play a higher card in that suit if he has it, being at his option although he is the last player, and the trick should belong to the ombre; but he is obliged to play in the suit led if he can, otherwise he renounces. If he separates a card from his game, and shows it, he is obliged to play it, if by not doing it the game may be prejudiced, or if it can give any intelligence to his friend; but especially if it should be a matadore.—He that plays *fans appeller*, or by calling himself, is not subject to this law. He may turn the tricks made by the other players, and count what has been played as often as it is his turn to play, but not otherwise. If instead of turning a player's tricks, he turns and sees his game, or shows it to the other players, he is beasted, together with him whose cards he turned; and each of them must pay one half of the beast.

If any one renounces, he is beasted as often as he has renounced and it is detected; but a renounce is not made till the trick is turned. If the renounce is discovered before the deal is finished, and has been detrimental to the game, the cards must be taken up again, and the game replayed from that trick where the renounce was made; but if the cards are all played, the beast is still made, and the cards must not be replayed; except there should be several renounces in the same deal: then they are to be played again, unless the cards should be mixed. If several beasts are made in the same deal, they all go together, unless it is otherwise agreed at the beginning of the party; and when there are several beasts, the greatest always goes first.

A great advantage accrues from being eldest hand at quadrille, which often renders it very disagreeable to the rest of the players, being obliged to pass with a good hand unless they choose to play alone; and when it happens that the eldest hand having asked leave, the second player has three matadores, several trumps in back, and all small cards, he cannot then even play alone; and having no chance of being called, he must pass with this good hand. On account of which, this method has been thought expedient to remedy this defect of the game; each player having an opportunity of availing himself of the goodness of his game, by adding to the usual method of playing the game that of the mediateur, and the favourite suit.

The first thing to be observed is that of drawing for places, which is done in this manner: One of the players takes four cards; a king, a queen, a knave, and an ace; each player draws one of these cards; and commonly he who comes in last, draws first. The person who draws the king sits where he pleases, the queen at his right hand, the knave next the queen, and the ace on the left of the king. The king draws the favourite suit. The number of cards and persons is the same at this game as the other, and is played in the same manner.

The favourite suit is determined by drawing a card out of the pack, and is of the same suit, during the whole party, of the card so drawn.

A king is the mediateur, which is demanded of the others by one of the players, who has a hand he expects

Quadrille
Quail.

pects to make five tricks of; and through the assistance of this king he can play alone and make six tricks.

In return for the king received, he gives what card he thinks proper with a fish; but must give two fish if it is in the favourite suit. He who asks by calling in the favourite suit, has the preference to him who asks by calling in any other; he who asks with the mediateur, has the preference to him who asks by calling in the favourite suit, and by playing alone is obliged to make six tricks to win. He who asks with the mediateur in the favourite suit, has the preference to him who asks with the mediateur in any other suit, and is obliged to play alone, and to make six tricks.

If fans prendre is played in any other suit than the favourite, he who plays it has the preference to him who asks only, or with the mediateur, or even he who plays in the favourite suit with the mediateur; and the fans prendre in the favourite suit has the preference to all other players whatever.

The only difference between this method of playing the game and the other is, that when one of the players demands the mediateur he is obliged to play alone, and to make six tricks, as if he played fans prendre. In this case he should judge from the strength of his hand, whether the aid of the king will enable him to play alone or not.

With the mediateur and without the favourite suit it is played in this manner. The game is marked and played the same as in common, except that a fish extraordinary is given to him who plays the mediateur, and to him who plays fans prendre; that is, he who wins the mediateur receives 13 counters from each; and if he loses by remise he pays 12 to each; and 13 if by codill. The winner of fans prendre receives 17 counters from each; and if by remise he loses, he pays 16 to each: and 17 if by codill.

The vole with the mediateur receives one fish only, as at common quadrille. The beats are also the same as the common game. The last game is generally played double, and is called *poulans*; but for those who choose to play a higher game, they may play the double colour, which is called the *Turk*, and is double of the favourite suit. There is also a higher game than this called the *auôde*, which is paying whatever is agreed to him who happens to hold the two aces in his hand.

We have omitted many things respecting the mode of marking the game, and playing the vole, because these are different in different cases, and are to be learned only by practice. The game itself is a very inferior one; but he who wishes to know more of it, may consult Hoyle's games improved by James Beaufort, Esq; from which we have, with very little alteration, taken this article.

QUADRUPEDS, in zoology; those animals which have four limbs or legs proceeding from the trunk of their body. See ZOOLOGY; in which article notice will be taken of the method of preserving specimens of these and other animals.

QUESTOR, see QUESTOR.

QUAGGA, or QUACHA See EQUUS, n° 5.

QUAIL, in zoology. See TETRAO.

Quails are to be taken by means of the call during their whole wooing time, which lasts from April to August. The proper times for using the call are at sun-rising, at nine o'clock in the morning, at three in

the afternoon, and at sun-set; for these are the natural times of the quail's calling. The notes of the cock and hen quail are very different; and the sportsman who expects to succeed in the taking them must be expert in both: for when the cock calls, the answer is to be made in the hen's note; and when the hen calls, the answer is to be made in the cock's. By this means they will come up to the person, so that he may, with great ease, throw the net over them and take them. If a cock-quail be single, on hearing the hen's note he will immediately come; but if he have a hen already with him, he will not forsake her. Sometimes, though only one quail answers to the call, there will three or four come up; and then it is best to have patience, and not run to take up the first, but stay till they are all entangled, as they will soon be.

The quail is a neat cleanly bird, and will not run much into dirty or wet places: in dewy mornings, they will often fly instead of running to the call; and in this case, it is best to let them go over the net, if it so happens that they fly higher than its top; and the sportsman then changing sides, and calling again, the bird will come back, and then will probably be taken in the net.

The calls are to be made of a small leather purse, about two fingers wide, and four fingers long, and made in the shape of a pear; this is to be stuffed half-full of horse-hair, and at the end of it is to be placed a small whistle, made of the bone of a rabbit's leg, or some other such bone: this is to be about two inches long, and the end formed like a flageolet, with a little soft wax. This is to be the end fastened into the purse; the other is to be closed up with the same wax, only that a hole is to be opened with a pin, to make it give a distinct and clear sound. To make this sound, it is to be held full in the palm of the hand, with one of the fingers placed over the top of the wax; then the purse is to be pressed, and the finger is to shake over the middle of it, to modulate the sound it gives into a sort of shake. This is the most useful call; for it imitates the note of the hen-quail, and seldom fails to bring a cock to the net if there be one near the place.

The call that imitates the note of the cock, and is used to bring the hen to him, is to be about four inches long, and above an inch thick; it is to be made of a piece of wire turned round and curled, and covered with leather; and one end of it must be closed up with a piece of flat wood, about the middle of which there must be a small thread or strap of leather, and at the other end is to be placed the same sort of pipe, made of bone, as is used in the other call. The noise is made by opening and closing the spiral, and gives the same sound that the cock does when he gives the hen a signal that he is near her.

QUAKERS, a religious society, which took its rise in England about the middle of the last century, and rapidly found its way into other countries in Europe, and into the English settlements in North America.—The members of this society, we believe, called themselves at first *seekers*, from their *seeking* the truth; but after the society was formed, they assumed the appellation of *friends*. The name of *quakers* was given to them by their enemies; and though an epithet of reproach, seems to be stamped upon them indelibly. Their founder

art. 5.

der is generally believed to have been George Fox, an illiterate shoemaker (see *George Fox*), but this opinion has been lately controverted. An ingenious writer ‡ having found, or fancied, a similarity of sentiments among the ancient Druids and modern Quakers, seems to think that Fox must have been nothing more than a tool employed by certain deists to pave the way for their system of natural religion, by allegorizing the distinguishing articles of the Christian faith.

It must be confessed, for experience will not allow it to be denied, that extremes in religion are very apt to beget each other; and if the deists alluded to reasoned from this fact, they could not have pitched upon a tool fitter for their purpose than George Fox. From his works still extant, he has been considered as one of the most extravagant and absurd enthusiasts that ever lived, and to have fancied himself, in his apostolic character, something infinitely superior to man. In a book called *News coming out of the North* (p. 15.) he says of himself, "I am the Door that ever was, the same Christ yesterday, to-day, and for ever:" And in the introduction to his *Battle-door for Teachers and Professors*, he says, "All languages are to me no more than dust, who was before languages were." But one of the most extraordinary and curious things that he ever wrote, is an answer to the Protector, who had required him to promise not to disturb his government as then established. It is as follows:

"I who am of the world called G: F doth deny the carrying or drawing any carnal sword against any, or against thee O: C: or any man, in the presence of the Lord I declare it, God is my witness, by whom I am moved to give this forth for the truth's sake, from him whom the world calls G: Fox, *who is the son of God*, who is sent to stand a witness against all violence and against the works of darkness, and to turn the people from darkness to light, and to bring them from the occasion of the war and from the occasion of the magistrates sword, which is a terror to the evil doer, which acts contrary to the light of the Lord *Jesus Christ*; which is a praise to them that do well; which is a protection to them that do well, and not the evil; and such soldiers as are put in place no false accusers must be, no violence must do, but be content with their wages: and that magistrate bears not the sword in vain, from under the occasion of that sword do I seek to bring people: my weapons are not carnal but spiritual, and *my kingdom is not of this world*; therefore with carnal weapon I do not fight, but am from those things dead, from him who is not of this world, called of the world by the name of G: F: and this I am ready to seal with my blood; this I am moved to give forth for the truth's sake, who a witness stands against all unrighteousness, and all ungodliness, who a sufferer is for the righteous seed's sake, waiting for the redemption of it, who a crown that is mortal seeks not, for that fadeth away;

but in the light dwells which comprehends that crown, which light is the condemnation of all such, in which light I witness the crown that is immortal, which fades not away from him who to all your souls is a friend, for establishing of righteousness, and clearing the land of evil doers, and a witness against all the wicked inventions of man, and murderer's plots, which answer shall be with the light in all your consciences, which makes no covenant with death; to which light in you all I speak, and am clear, G: F: who a new name hath, which the world knows not." (A).

The Quakers, however, did not long entrust the defence of their principles to such senseless enthusiasts as George Fox: They were joined by a number of learned, ingenious, and pious men, who new-modelled their creed; and though they did not bring it to what is generally deemed the Christian standard, they so reformed it as that its tenets do not shock common sense, nor the duties prescribed scandalize a man of piety. The chief of these reformers were George Keith, the celebrated Penn, and Robert Barclay. Keith was indeed excommunicated for the liberties which he took with the great apostle; but we have not a doubt but his writings contributed to the moderation of Penn, and to the elegant and masterly apology of Barclay. From that apology we selected the summary of their opinions which was given in the former edition of this work; but they have lately published such a summary themselves, of which the reader will be pleased with the following abstract:

They tell us, that about the beginning of the 17th century, a number of men, dissatisfied with all the modes of religious worship then known in the world, withdrew from the communion of every visible church to seek the Lord in retirement. Among these was their *honourable elder George Fox*, who being quickened by the immediate touches of divine love, could not satisfy his apprehensions of duty to God without directing the people where to find the like consolation and instruction. In the course of his travels, he met with many seeking persons in circumstances similar to his own, and these readily received his testimony. They then give us a short account of their sufferings and different settlements; and with a degree of candour which does them great credit, they vindicate Charles II. from the character of a persecutor; acknowledging, that though they suffered much during his reign, he gave as little countenance as he could to the severities of the legislature. They even tell us, that he exerted his influence to rescue their friends from the unprovoked and cruel persecutions of the New England fanatics; and they speak with becoming gratitude of the different acts passed in their favour during the reigns of William and Mary, and George I. They then proceed to give us the following account of their doctrine:

"We

(A) We have transcribed this letter from the theological works of Mr Leslie, where it is preserved in its original form. The Quakers, after the death of their apostle, expunged from their edition of it the words which we have printed in Italics; ashamed, as we hope, of the blasphemy imputed to them: but that Mr Leslie's copy is authentic, is thus attested by two of the friends, who saw Fox deliver it to the protector's messenger: "We are witnesses of this testimony, whose names in the flesh are,

Tho. Aldam.
Rob. Craven.

Quakers.

Quakers.

"We agree with other professors of the Christian name, in the belief in one eternal God, the Creator and Preserver of the universe; and in Jesus Christ his Son, the Messiah, and Mediator of the new covenant (Heb. xii. 24).

"When we speak of the gracious display of the love of God to mankind, in the miraculous conception, birth, life, miracles, death, resurrection, and ascension of our Saviour, we prefer the use of such terms as we find in Scripture; and, contented with that knowledge which divine wisdom hath seen meet to reveal, we attempt not to explain those mysteries which remain under the veil; nevertheless, we acknowledge and assert the divinity of Christ, who is the wisdom and power of God unto salvation (1 Cor. i. 24).

"To Christ alone we give the title of the Word of God (John i. 1.) and not to the Scriptures; although we highly esteem these sacred writings, in subordination to the Spirit (2 Pet. i. 21.), from which they were given forth; and we hold, with the apostle Paul, that they are able to make wise unto salvation, through faith which is in Christ Jesus (2 Tim. iii. 15).

"We reverence those most excellent precepts which are recorded in Scripture to have been delivered by our great Lord, and we firmly believe that they are practicable, and binding on every Christian; and that in the life to come every man will be rewarded according to his works (Mat. xvi. 27). And farther, it is our belief, that, in order to enable mankind to put in practice these sacred precepts, many of which are contradictory to the unregenerate will of man (John i. 9.), every man coming into the world is endued with a measure of the light, grace, or good Spirit of Christ; by which, as it is attended to, he is enabled to distinguish good from evil, and to correct the disorderly passions and corrupt propensities of his nature, which mere reason is altogether insufficient to overcome. For all that belongs to man is fallible, within the reach of temptation; but this divine grace, which comes by Him who hath overcome the world (John xvi. 33.) is, to those who humbly and sincerely seek it, an all-sufficient and present help in time of need. By this the snares of the enemy are detected, his allurements avoided, and deliverance is experienced through faith in its effectual operation; whereby the soul is translated out of the kingdom of darkness, and from under the power of Satan, into the marvellous light and kingdom of the Son of God.

"Being thus persuaded that man, without the Spirit of Christ inwardly revealed, can do nothing to the glory of God, or to effect his own salvation; we think this influence especially necessary to the performance of the highest act of which the human mind is capable, even the worship of the Father of lights and of spirits, in spirit and in truth; therefore we consider as obstructions to pure worship, all forms which divert the attention of the mind from the secret influence of the unction from the Holy One (1 John ii. 20, 27). Yet, although true worship is not confined to time and place, we think it incumbent on Christians to meet often together (Heb. x. 25.) in testimony of their dependence on the heavenly Father, and for a renewal of their spiritual strength; nevertheless, in the performance of worship, we dare not depend, for our acceptance with Him, on a formal repetition of the words and experiences of others; but we believe it to be our duty to cease from

the activity of the imagination, and to wait in silence to have a true light of our condition bestowed upon us: believing even a single sigh (Rom. viii. 26.) arising from such a sense of our infirmities, and of the need we have of divine help, to be more acceptable to God, than any performances, however specious, which originate in the will of man.

"From what has been said respecting worship, it follows, that the ministry we approve must have its origin from the same source: for that which is needful for a man's own direction, and for his acceptance with God (Jer. xxiii. 30, to 32.) must be eminently so to enable him to be helpful to others. Accordingly, we believe the renewed assistance of the light and power of Christ to be indispensably necessary for all true ministry; and that this holy influence is not at our command, or to be procured by study, but is the free gift of God to his chosen and devoted servants.—From hence arises our testimony against preaching for hire, and in contradiction to Christ's positive command, "Freely ye have received, freely give;" (Mat. x. 8.) and hence our conscientious refusal to support such ministry by tithes or other means.

"As we dare not encourage any ministry but that which we believe to spring from the influence of the Holy Spirit, so neither dare we attempt to restrain this influence to persons of any condition in life, or to the male sex alone; but, as male and female are one in Christ, we allow such of the female sex as we believe to be endued with a right qualification for the ministry, to exercise their gifts for the general edification of the church: and this liberty we esteem to be a peculiar mark of the gospel dispensation, as foretold by the prophet Joel (Joel ii. 28, 29.) and noticed by the apostle Peter (Acts ii. 16, 17).

"There are two ceremonies in use amongst most professors of the Christian name; Water baptism, and what is termed the Lord's Supper. The first of these is generally esteemed the essential means of initiation into the church of Christ; and the latter of maintaining communion with him. But as we have been convinced, that nothing short of his redeeming power, inwardly revealed, can set the soul free from the thralldom of sin, by this power alone we believe salvation to be effected. We hold that as there is one Lord and one faith (Eph. iv. 5.), so his baptism is one in nature and operation; that nothing short of it can make us living members of his mystical body; and that the baptism with water, administered by his fore-runner John, belonged, as the latter confessed, to an inferior and decreasing dispensation (John iii. 30).

"With respect to the other rite, we believe that communion between Christ and his church is not maintained by that nor any other external performance, but only by a real participation of his divine nature (2 Pet. i. 4.) through faith; that this is the supper alluded to in the Revelation (Rev. iii. 20.), "Behold I stand at the door and knock, if any man hear my voice, and open the door, I will come in to him, and will sup with him, and be with me;" and that where the substance is attained, it is unnecessary to attend to the shadow, which doth not confer grace, and concerning which opinions so different, and animosities so violent, have arisen.

"Now, as we thus believe that the grace of God, which comes by Jesus Christ, is alone sufficient for salvation,

Quakers.

Quakers.

vation, we can neither admit that it is conferred on a few only, whilst others are left without it; nor, thus asserting its universality, can we limit its operation to a partial cleansing of the soul from sin, even in this life. We entertain worthier notions both of the power and goodness of our heavenly Father, and believe that he doth vouchsafe to assist the obedient to experience a total surrender of the natural will to the guidance of his pure unerring Spirit; through whose renewed assistance they are enabled to bring forth fruits unto holiness, and to stand perfect in their present rank (Mat. v. 48.; Eph. iv. 13.; Col. iv. 12.)

• See Oath. "There are not many of our tenets more generally known than our testimony against oaths and against war. With respect to the former of these, we abide literally by Christ's positive injunction, delivered in his sermon on the mount, "Swear not at all" (Mat. v. 34)*. From the same sacred collection of the most excellent precepts of moral and religious duty, from the example of our Lord himself (Mat. ch. v. 39, 44, &c. ch. xxvi. 52, 53.; Luke xxii. 51.; John xviii. 11.), and from the correspondent convictions of his Spirit in our hearts, we are confirmed in the belief that wars and fightings are, in their origin and effects, utterly repugnant to the Gospel, which still breathes peace and good-will to men. We also are clearly of the judgment, that if the benevolence of the Gospel were generally prevalent in the minds of men, it would effectually prevent them from oppressing, much more from enslaving, their brethren, (of whatever colour or complexion), for whom, as for themselves, Christ died; and would even influence their conduct in their treatment of the brute creation, which would no longer groan the victims of their avarice, and of their false ideas of pleasure.

"Some of our tenets have in former times, as hath been shown, subjected our friends to much suffering from government, though to the salutary purposes of government our principles are a security. They inculcate submission to the laws in all cases wherein conscience is not violated. But we hold, that as Christ's kingdom is not of this world, it is not the business of the civil magistrate to interfere in matters of religion; but to maintain the external peace and good order of the community. We therefore think persecution, even in the smallest degree, unwarrantable. We are careful in requiring our members not to be concerned in illicit trade, nor in any manner to defraud the revenue.

"It is well known that the society, from its first appearance, has disused those names of the months and days which, having been given in honour of the heroes or false gods of the heathens, originated in their flattery or superstition; and the custom of speaking to a single person in the plural number (b), as having arisen also from motives of adulation. Compliments, superfluity of apparel and furniture, outward shows of rejoicing and mourning, and observation of days and times, we esteem to be incompatible with the simplicity and sincerity of a Christian life; and public diversions, gaming, and other vain amusements of the world, we cannot but condemn. They are a waste of that time

Quakers. which is given us for nobler purposes, and divert the attention of the mind from the sober duties of life, and from the reproofs of instruction, by which we are guided to an everlasting inheritance.

"To conclude, although we have exhibited the several tenets which distinguish our religious society, as objects of our belief, yet we are sensible that a true and living faith is not produced in the mind of man by his own effort; but is the free gift of God (Eph. ii. 8.) in Christ Jesus, nourished and increased by the progressive operation of his spirit in our hearts, and our proportionate obedience (John vii. 17.) Therefore, although, for the preservation of the testimonies given us to bear, and for the peace and good order of the society, we deem it necessary that those who are admitted into membership with us, should be previously convinced of those doctrines which we esteem essential; yet we require no formal subscription to any articles, either as the condition of membership, or to qualify for the service of the church. We prefer the judging of men by their fruits, in a dependence on the aid of Him who, by his prophet, hath promised to be "a spirit of judgment to him that sitteth in judgment" (Isaiah xxviii. 6.) Without this, there is a danger of receiving numbers into outward communion, without any addition to that spiritual sheepfold, whereof our blessed Lord declared himself to be both the door and the shepherd (John x. 7, 11.) that is, such as know his voice, and follow him in the paths of obedience."

Such are the doctrines of this people as we find them stated in a small pamphlet lately presented by themselves to the public; and in the same tract they give the following account of their discipline.

"In the practice of discipline, we think it indispensable that the order recommended by Christ himself be invariably observed: (Matth. xviii. 15. to 17.) 'If thy brother shall trespass against thee, go and tell him his fault between thee and him alone: if he shall hear thee, thou hast gained thy brother; but if he will not hear thee, then take with thee one or two more, that in the mouth of two or three witnesses every word may be established; and if he shall neglect to hear them, tell it unto the church.'

"To effect the salutary purposes of discipline, meetings were appointed, at an early period of the society, which, from the times of their being held, were called quarterly-meetings. It was afterwards found expedient to divide the districts of those meetings, and to meet more often; whence arose monthly-meetings, subordinate to those held quarterly. At length, in 1669, a yearly-meeting was established, to superintend, assist, and provide, rules for the whole; previous to which, general meetings had been occasionally held.

"A monthly-meeting is usually composed of several particular congregations, situated within a convenient distance of each other. Its business is to provide for the subsistence of their poor, and for the education of their offspring; to judge of the sincerity and fitness of persons appearing to be convinced of the religious principles of the society, and desiring to be admitted into

(b) Speaking of this custom, Fox says: "When the Lord sent me into the world, he forbade me to put off my hat to any; and I was required to *thee* and *thou* all men and women." *Journal*, p. 24.

Quaker.

into membership ; to excite due attention to the discharge of religious and moral duty ; and to deal with disorderly members. Monthly meetings also grant to such of their members as remove into other monthly meetings, certificates of their membership and conduct ; without which they cannot gain membership in such meetings. Each monthly-meeting is required to appoint certain persons under the name of *oversiders*, who are to take care that the rules of our discipline be put in practice ; and when any case of complaint or disorderly conduct comes to their knowledge, to see that private admonition, agreeable to the gospel rule before-mentioned, be given previous to its being laid before the monthly-meeting.

“ When a case is introduced, it is usual for a small committee to be appointed to visit the offender, to endeavour to convince him of his error, and to induce him to forsake and condemn it. If they succeed, the person is by minute declared to have made satisfaction for the offence ; if not, he is disowned as a member of the society.

“ In disputes between individuals, it has long been the decided judgement of the society that its members should not sue each other at law. It therefore enjoins all to end their differences by speedy and impartial arbitration, agreeable to rules laid down. If any refuse to adopt this mode, or, having adopted it, to submit to the award, it is the direction of the yearly-meeting that such be disowned.

“ To monthly-meetings also belongs the allowing of marriages ; for our society hath always scrupled to acknowledge the exclusive authority of the priests in the solemnization of marriage. Those who intend to marry, appear together and propose their intention to the monthly meeting ; and if not attended by their parents or guardians, produce a written certificate of their consent, signed in the presence of witnesses. The meeting then appoints a committee to enquire whether they are clear of other engagements respecting marriage ; and if at a subsequent meeting to which the parties also come and declare the continuance of their intention, no objections are reported, they have the meeting’s consent to solemnize their intended marriage. This is done in a public meeting, for worship ; towards the close whereof the parties stand up, and solemnly take each other for husband and wife. A certificate of the proceeding is then publicly read, and signed by the parties, and afterwards by the relations and others as witnesses. Of such certificates the monthly-meeting keeps a record ; as also of the births and burials of its members. A certificate of the date, of the name of the infant, and of its parents, signed by those present at the birth, is the subject of one of these last-mentioned records ; and an order for the interment, counter-signed by the grave-maker, of the other. The naming of children is without ceremony. Burials are

Vol. XV.

also conducted in a simple manner. The body, followed by the relations and friends, is sometimes, previously to interment, carried to a meeting ; and at the grave a pause is generally made ; on both which occasions it frequently falls out that one or more friends present have somewhat to express for the edification of those who attend ; but no religious rite is considered as an essential part of burial.

“ Several monthly-meetings compose a quarterly-meeting. At the quarterly meeting are produced written answers from the monthly-meetings, to certain queries respecting the conduct of their members, and the meeting’s care over them. The accounts thus received are digested into one, which is sent, also in the form of answers to queries, by representatives, to the yearly-meeting.—Appeals from the judgement of monthly-meetings are brought to the quarterly-meetings ; whose business also it is to assist in any difficult case, or where remissness appears in the care of the monthly-meetings over the individuals who compose them.

“ The yearly-meeting has the general superintendence of the society in the country in which it is established (c) ; and therefore, as the accounts which it receives discover the state of inferior meetings, as particular exigencies require, or as the meeting is impressed with a sense of duty, it gives forth its advice, makes such regulations as appear to be requisite, or excites to the observance of those already made ; and sometimes appoints committees to visit those quarterly-meetings, which appear to be in need of immediate help. Appeals from the judgement of quarterly-meetings are here finally determined ; and a brotherly correspondence, by epistles, is maintained with other yearly-meetings.

“ In this place it is proper to add, that as we believe women may be rightly called to the work of the ministry, we also think, that to them belongs a share in the support of our Christian discipline ; and that some parts of it, wherein their own sex is concerned, devolve on them with peculiar propriety. Accordingly they have monthly, quarterly, and yearly-meetings of their own sex, held at the same time and in the same place with those of the men : but separately, and without the power of making rules : and it may be remarked, that during the persecutions, which in the last century occasioned the imprisonment of so many of the men, the care of the poor often fell on the women, and was by them satisfactorily administered.

“ In order that those who are in the situation of ministers may have the tender sympathy and counsel of those of either sex, who, by their experience in the work of religion, are qualified for that service ; the monthly-meeting are advised to select such, under the denomination of *elders*. These, and ministers approved by their monthly-meetings (d), have meetings peculiar to themselves, called meetings of ministers and elders ;

5 A in

(c) “ There are seven yearly-meetings, viz. 1st, London, to which come representatives from Ireland ; 2d, New-England ; 3d, New-York ; 4th, Pennsylvania and New-Jersey ; 5th, Maryland ; 6th, Virginia ; 7th the Carolinas and Georgia.”

(d) “ Those who believe themselves required to speak in meetings for worship, are not immediately acknowledged as ministers by their monthly-meetings ; but time is taken for judgement, that the meeting may be satisfied of their call and qualification. It will also sometimes happen, that such as are not approved, will obtrude themselves as ministers, to the grief of their brethren ; but much forbearance is used towards these, before the disapprobation of the meeting is publicly testified.”

Quaker.

Quaker. in which they have an opportunity of exciting each other to a discharge of their several duties, and of extending advice to those who may appear weak, without any needless exposure. These meetings are generally held in the compass of each monthly, quarterly, and yearly-meeting. They are conducted by rules prescribed by the yearly-meeting, and have no authority to make any alteration or addition to them. The members of them unite with their brethren in the meetings for discipline, and are equally accountable to the latter for their conduct.

"It is to a meeting of this kind held in London, called the second-day morning-meeting, that the revival of manuscripts concerning our principles, previously to publication, is intrusted by the yearly-meeting held in London; and also the granting, in the intervals of the yearly-meeting, certificates of approbation to such ministers as are concerned to travel in the work of the ministry in foreign parts. When a visit of this kind doth not extend beyond Great Britain, a certificate from the monthly-meeting of which the minister is a member is sufficient; if to Ireland, the concurrence of the quarterly-meeting is also required. Regulations of similar tendency obtain in other yearly-meetings.

"The yearly-meeting held in London, in the year 1675, appointed a meeting to be held in that city, for the purpose of advising and assisting in cases of suffering for conscience sake, which hath continued with great use to the society to this day. It is composed of friends under the name of correspondents, chosen by the several quarterly-meetings, and who reside in or near the city. The same meetings also appoint members of their own in the country as correspondents, who are to join their brethren in London on emergency. The names of all these correspondents, previous to their being recorded as such, are submitted to the approbation of the yearly-meeting. Those of the men who are approved ministers are also members of this meeting, which is called the *meeting for sufferings*; a name arising from its original purpose, which is not yet become entirely obsolete.

"The yearly-meeting has intrusted the meeting for sufferings with the care of printing and distributing books, and with the management of its stock; and considered as a standing committee of the yearly-meeting, it hath a general care of whatever may arise, during the intervals of the meeting, affecting the society, and requiring immediate attention: particularly of those circumstances which may occasion an application to government.

"There is not in any of the meetings which have been mentioned any president, as we believe that Divine Wisdom alone ought to preside; nor hath any member a right to claim pre-eminence over the rest. The office of clerk, with a few exceptions, is undertaken voluntarily by some member; as is also the keeping of the records. Where there are very voluminous, and require a house for their deposit (as is the case in London, where the general records of the society in Great Britain are kept), a clerk is hired to have the care of them; but except a few clerks of this kind, and persons who have the care of meeting-houses, none receive any stipend or gratuity for their services in our religious society."

It is remarkable, that all the settlements of the Europeans in America, except the Quaker settlement of Pennsylvania, were made by force of arms, with very little regard to any prior title in the natives. The kings of Spain, Portugal, France, and Britain, together with the States of Holland, then the only maritime powers, gave grants of such parts of America as their people could lay hold on, studying only to avoid interference with their European neighbours. But Mr Penn, being a Quaker, did not think his power from King Cha. II. a sufficient title to the country since called *Pennsylvania*: He therefore assembled the sachems or princes then in that country, and purchased from them the extent of land that he wanted. The government of this province was long in the hands of the quakers, who never have any quarrels with the natives. When they desired to extend their settlements, they purchased new lands of the sachems, never taking any thing from them by force. How unlike is this conduct to that of the Spaniards, who murdered millions of the natives of Mexico, Terra Firma, Peru, Chili, &c.

QUALITY is a word which, as used in philosophical disquisitions, cannot be explained by any periphrasis. That which is expressed by it must be brought into the immediate view of the senses or intellect, and the name properly applied, or he who is a stranger to the word will never be made to comprehend its meaning. Aristotle, who treated it as a general conception second in order among the ten *predicaments* or *categories* (see *CATEGORY*), gives several characters of it; but though they are all in some respects just, no man could from them, without other assistance, learn what *quality* is. Thus he tells us*, *ἡ ἀρετή ἐστὶν ἐναντιότης κατὰ τὸ ποιοῦν; ἐπιδέχεται δὲ τὸ μᾶλλον καὶ τὸ ἥττον τὰ ποιεῖν*. And again, *ὁμοία δὲ ἡ ἀρετή κατὰ μόναν τὰς ποιότητας λέγεται; ὁμοίον γὰρ ἕτερον ἕτερον οὐκ ἐστὶ κατ' ἄλλο οὐδέν, ἢ καὶ ὁ ποιοῦν ἐστίν*.

When a man comprehends, by means of his senses and intellect, what it is which the word *quality* denotes, he will indeed perceive that the first of these characters is applicable to some qualities and not to others; that the second is more applicable to *quantity* than to *quality*; and that it is only the third which can with propriety be considered as the general characteristic of this predicament. Thus when we have learned by our sense of sight that *whiteness* is a quality of snow, and *blackness* of coal; and by means of observation and reflection, that *wisdom* is a quality of one man and *folly* of another—we must admit that the sensible quality of the snow is *contrary* to that of the coal, and the intellectual quality of wisdom contrary to that of folly. There is, however, no contrariety between *wisdom* and *whiteness* or *blackness*, nor between *hardness* or *softness*, and *any particular colour*; for sensible and intellectual qualities can never be compared; and it is not easy, if possible, to make a comparison between qualities perceptible only by different senses: Nay, among qualities perceptible by the same sense, we often meet with a difference where there is no contrariety; for though the *figure* of a *cube* is *different* from that of a *sphere*, and the figure of a *square* from that of a *circle*, the sphere is not *contrary* to the cube, nor the circle to the square.

His second characteristic of this genus is still less proper than the first. It is indeed true that some qualities admit of *intension* and *remission*; for snow is whiter than paper, and one woman is handsomer than another; but

Quality.

Quality characterized by Aristotle.

* Præd. ed. Sylb. p. 44. 45.

Quality.

of the species of quality called *figure* we cannot predicate either *more* or *less*. A crown-piece may have as much of the *circular quality* in it as the plane of the equator, and a musket-bullet as much of the *spherical quality* as the orb of the sun. It is indeed a property of all *quantity* to admit of *intension* and *remission*; and therefore this ought to have been given as the character not of the second but of the third category. See QUANTITY.

2
Nothing known but qualities.

That it is only from a *comparison of their qualities that things are denominated like or unlike* or that *one thing cannot resemble another but in some quality*, is indeed a just observation. We know nothing directly but qualities sensible and intellectual (see METAPHYSICS, n° 149, 150, 151, and 227); and as these have no resemblance to each other, we conclude that body or matter, the subject of the former, is a being unlike mind, the subject of the latter. Even of bodies themselves we can say, that one is like or unlike another only by virtue of their qualities. A ball of ivory resembles a ball of snow in its *figure* and *colour*, but not in its *coldness* or *hardness*; a ball of lead may resemble a ball of snow in its *figure* and *coldness*, but not in its *colour*; and a cube of ivory resembles not a ball of lead either in *figure*, *colour*, or *coldness*. The mind of a brute resembles that of a man in its powers of *sensation* and *perception*, but does not resemble it in the powers of *volition* and *reasoning*; or at least, the resemblance, in this latter instance, is very slight. All bodies resemble one another in being solid and extended, and all minds in being more or less active. *Likeness* or *unlikeness* therefore is the universal characteristic of the category *quality*.

3
Important distinctions of quality,

Aristotle has other speculations respecting quality, which are worthy of notice. He distinguishes between qualities which are *essential* and those which are *accidental*; between qualities which are *natural* and those which are *acquired*; and he speaks of the qualities of *capacity* and those of *completion*. *Extension* and *figure* in general are qualities essential to all bodies; but a *particular extension*, such as an *inch* or an *ell*, and a *particular figure*, such as a *cube* or a *sphere*, are qualities accidental to bodies. Among the *natural* qualities of glass it is one to transmit objects of vision; but to enlarge these objects is an *adventitious* or *acquired* quality. The same quality may be *natural* in one substance, as attraction in the magnet; and *acquired* in another, as the same attraction in the magnetic bar. *Docility* may be called a quality *natural* to the mind of man, science an *acquired* one. To understand what he means by qualities of *capacity* and *completion*, it may be sufficient to observe that every piece of iron has the qualities of a razor in *capacity*, because it may be converted into steel, and formed into a razor: when it is so formed, it has, in the language of this sage, the quality of a razor in *completion*. Among the qualities of *capacity* and *completion*, the most important, and what may lead to interesting speculations, is the reasoning faculty of man. A *capacity* of reasoning is essential to the human mind; but the *completion* of this capacity or *actual reasoning* is not, otherwise *infants* and persons *asleep* would be excluded from the human species.

4
Overlooked by Locke.
* Book iv. ch. 4. § 13. &c.

Mr Locke has puzzled his readers, and perhaps himself, with a question respecting the species of an idiot or changeling, whom he pronounces to be something between a man and brute*. It is not often that we

feel ourselves inclined to regret Locke's ignorance of Aristotle's distinctions; but we cannot help thinking, that had the British philosopher attended to the Stagyrte's account of qualities in *capacity* and qualities in *completion*, this perplexing question would never have been started. It is justly observed in the *Essay on Human Understanding*, that of *real essences* we know nothing: but that every man selects a certain number of qualities which he has always perceived united in certain beings; and forming these into one complex conception, gives to this conception a *specific* name, which he applies to every being in which he finds those qualities united. This is undoubtedly the process of the mind in forming genera and species; and as the excellent author refuses the name of *man* to the changeling, it is obvious that the complex conception, to which he gives that name, must imply *rationality* or the *actual exercise* of reason. But this limitation will exclude many beings from the species *man*, whom Mr Locke certainly considered as men and women. Not to mention infants and persons in sound sleep, how shall we class those who, after having lived 30 or 40 years in the full exercise of reason, have been suddenly or by degrees deprived of it by some disorder in the brain?

From Marlborough's eyes the streams of dotage flow;
And Swift expires a driveller and a show.

JOHNSON.

But were the hero and the wit in those deplorable circumstances excluded from the human species, and classed between men and brutes? No surely; they were both acknowledged to be men, because they were known to have the quality of reason in what Aristotle would have called *capacity*. Their dotage and drivelling originated from some disorder in their bodies, probably in the region of the brain; and Locke himself contends that no defect in body is sufficient to degrade a person from the rank of manhood. Again, lunatics have the exercise of reason, except at new and full moon. Are these unhappy beings sometimes men and sometimes a species by themselves between men and brutes?

It appears, therefore, that *not the actual exercise* of reason, but reason in *capacity*, ought to be included in the complex conception to which we give the specific name of *man*, as some of the greatest men that ever lived have been during parts of their lives deprived of the power of *actual reasoning*. This, however, it will be said, does not remove the difficulty; for the occasional exercise of reason in lunatics, and the great exertions of it in such men as Swift and Marlborough, show that they had it in *capacity* at all times; whereas we have no evidence that changelings have even a *capacity* of reasoning at any time, since they never do a rational action, nor ever utter a sentence to the purpose. That we have no *direct* and *positive* evidence of the minds of changelings being capable of reasoning, were they supplied with proper organs, must be granted; but the probabilities of their being so are many and great. We know by experience that the actual exercise of reason may be interrupted by an occasional and accidental pressure on the brain: and therefore we cannot doubt but that if this pressure were rendered permanent by any wrong configuration of the skull given to it, in the womb, or in the act of being born into the world, an infant, with a mind capable of reasoning by means of proper organs,

5 A 2

would

Quality

trine.

would by this accident be rendered, through the whole of life, an idiot or changeling. That idiotism is caused by such accidents, and is not the quality of an inferior mind occasionally given to a human body, will at least seem probable from the following considerations.

It does not appear that an animal body can live and move but while it is actuated by some mind. Whence then does the unborn infant derive its mind? It must be either immediately from God, or *ex traduce* from its parents; but if the mind of man be immaterial, it cannot be *ex traduce*. Now, as idiots are very few in number when compared with the rational part of the human species, and as God in the government of this world acts not by partial but by general laws; we must conclude that the law which he has established respecting the union of mind and matter, is, that human bodies shall be animated with minds endowed with a capacity of reasoning, and that those who never exert this capacity are prevented by some such accident as we have assigned.

For a further account of qualities, why they are supposed to inhere in some subject, together with the usual distinction between the primary and secondary qualities of matter, see METAPHYSICS, Part II. Chap. I.

Chemical QUALITIES, those qualities principally introduced by means of chemical experiments, as fumigation, amalgamation, cupellation, volatilization, precipitation, &c.

QUALITY, is also used for a kind of title given to certain persons, in regard of their territories, signiorities, or other pretensions.

QUANGA. See CAPRA.

QUANG-PING-FOU, a city in China, is situated in the northern part of the province of Pe-tcheli, between the provinces of Chang-tong and Ho-nan, and has nine cities of the third class dependent on it; all its plains are well watered by rivers. Among its temples, there is one dedicated to those men who, as the Chinese pretend, discovered the secret of rendering themselves immortal.

QUANGSI, a province of China, bounded on the north by Koe-Tcheau and Hu-Quang; on the east, by Yunan and Quantong; on the south, by the same and Ton-quin; and on the west, by Yun-nan. It produces great plenty of rice, being watered by several large rivers. The southern part is a flat country, and well cultivated; but the northern is full of mountains covered with trees. It contains mines of all sorts; and there is a gold-mine lately opened. The capital town is Quie-ling.

A very singular tree, says Grosier, grows in this province; instead of pith, it contains a soft pulp, which yields a kind of flour: the bread made of it is said to be exceedingly good. Besides paroquets, hedgehogs, porcupines, and rhinoceroses, a prodigious number of wild animals, curious birds, and uncommon insects, are found here.

This province contains 12 villages of the first class, and 80 of the second and third.

QUANG-RONG, a province of China, bounded on the east by Kiang-si and Fokien; on the south, by the ocean; and on the west, by Ton-quin. This province is diversified by valleys and mountains; and yields two crops of corn in a year. It abounds in gold, jewels, silk, pearls, tin, quicksilver, sugar, brass, iron, steel, salt-

petre, ebony, and several sorts of odoriferous wood; besides fruits of all sorts proper to the climate. They have a prodigious number of ducks, whose eggs they hatch in ovens; and a tree, whose wood is remarkably hard and heavy, and thence called *iron-wood*. The mountains are covered with a sort of oysters which creep along the ground, and of which they make baskets, hurdles, matts, and ropes.

Although the climate of this province is warm, the air is pure, and the people are robust and healthy. They are very industrious; and it must be allowed that they possess in an eminent degree the talent of imitation: if they are only shown any of the European works, they execute others like them with the most surprising exactness. This province suffered much during the civil wars; but at present it is one of the most flourishing in the empire; and, as it is at a great distance from court, its government is one of the most important. This province is divided into ten districts, which contain 10 cities of the first class, and 84 of the second and third. Canton is the capital town.

QUANTITY, as explained by the great English lexicographer, is that property of any thing which may be increased or diminished. This interpretation of the word is certainly just, and for the purposes of common conversation it is sufficiently determinate; but the man of science may expect to find in a work like ours a definition of the thing signified. This, however, cannot be given him. A logical definition consists of the *genus* under which the thing defined is ranked, and the *specific* difference (see LOGIC, n° 20, &c.); but quantity is ranked under no genus. In that school where such definitions were most valued, it was considered as one of the ten *categories*, or general conceptions, under which all the objects of human apprehension were mustered, like soldiers in an army (see CATEGORY and PHILOSOPHY, n° 22.) On this account, even Aristotle himself, who delighted in definitions, and was not easily deterred from a favourite pursuit, could not consistently with his own rules attempt to define *quantity*. He characterized it, however, in several parts of his works; and particularly in the 15th chapter of the 4th book of his metaphysics, where he gives the following account of the three first *categories*: ΤΑΥΤΑ ΜΕΝ ἓς, ὡς μὴ τ' οὐσία. ὁμοία δ' ὡς τ' πρὸς τὴν μίαν ἰσὰ δὲ ὡς πρὸς τὸν ἓν. "Things are the same, of which the SUBSTANCE is one: *similar*, of which the QUALITY is one; *equal*, of which the QUANTITY is one. Again, he tells us*, that the chief characteristic of quantity is, that it may be denominated *equal* and *unequal*.

That any man can become wiser by reading such descriptions as these, none but an idolater of Aristotle will suppose. There is, indeed, no periphrasis by which we can explain what is meant by quantity to those who have not previously formed such a notion.—All that can be done by making the attempt is only to settle language, by stating exactly the cases in which we use this word in the greatest conformity to general custom; for there is a laxness or carelessness of expression in the language of most men, and our notions are frequently communicated by speech in a way by no means precise; so that it is often a great chance that the notions excited in the mind of the hearer are not exact counterparts of those in the mind of the speaker.

The

Quantity.

The understandings of men differ in nothing more remarkably than in their power of abstraction, and of rapidly forming conceptions so general and simple as not to be clogged with distinguishing circumstances, which may be different in different minds while uttering and hearing the same words: and it is of great consequence to a man of scientific habits, either to cultivate, if possible, this talent, or to supersede its use, by studiously forming to himself notions of the most important *universals* in his own course of contemplation, by careful abstraction of every thing extraneous. His language by this means becomes doubly instructive by its extreme precision; and he will even judge with greater certainty of notions intended to be communicated by the more slovenly language of another person.

We cannot say that there is much ambiguity in the general use of the term *quantity*: But here, as in all other cases, a love of refinement, of novelty, and frequently of vanity, and the wish of appearing ingenious and original, have made men take advantage of even the small latitude with which the careless use of the word will furnish them, to amuse themselves and the public by giving the appearance of science to empty sounds.

³
The subject
of mathe-
matical
reasoning.

Mathematics is undoubtedly employed in discovering and stating many relations of quantity; and it is in this category alone that any thing is contemplated by the mathematician, whether in geometry, arithmetic, or algebra. Hence mathematics has been called the science of quantity. The simplicity of the object of the mathematician's contemplation, and the unparalleled distinctness with which he can perceive its modifications, have enabled him to erect a body of science, eminent not only for its certainty, but also for the great length to which he can carry his reasonings without danger of error; and the intimate connection which this science has with the arts of life, and the important services which it has performed, have procured it a most respectable place in the circle of the sciences. Ingenious men have availed themselves of this pre-eminence of mathematics, and have endeavoured to procure respect for their disquisitions on other subjects, by presenting them to the public as branches of mathematical science, and therefore susceptible of that accuracy and certainty which are its peculiar boast. Our moral affections, our sensations, our intellectual powers, are all susceptible of augmentation and diminution, are conceivable as greater and less when stated together, and are familiarly spoken of as admitting of degrees of comparison. We are perfectly well understood when we say that one pain, heat, grief, kindness, is greater than another; and as this is the distinguishing characteristic of quantity, and as quantity is the subject of mathematical discussion, we suppose that these subjects may be treated mathematically. Accordingly, a very celebrated and excellent philosopher* has said, among many things of the same

* Dr Francis Hut-
chinson.

kind, that the greatness of a favour is in the direct compound ratio of the service performed and the dignity of the performer, and the inverse ratio of the merit and rank of the receiver; that the value of a character is in the compound ratio of the talents and virtue, &c.; and he has delivered a number of formal propositions on the most interesting questions in morals, couched in this mathematical language, and even expressed by algebraic formulæ. But this is mere play, and conveys no instruction. We understand the words; they contain no absurdity; and in as far as they have a sense, we believe the propositions to be true. But they give no greater precision to our sentiments than the more usual expressions would do. If we attend closely to the meaning of any one of such propositions, we shall find that it only expresses some vague and indistinct notions of degrees of those emotions, sentiments, or qualities, which would be just as well conceived by means of the expressions of ordinary language; and that it is only by a sort of analogy or resemblance that this mathematical language conveys any notions whatever of the subjects.

The object of contemplation to the mathematician is not whatever is susceptible of greater and less, but what is measurable; and mathematics is not the science of magnitude, in its most abstracted and general acceptation, but of magnitude which can be measured. It is, indeed, the science of measure, and whatever is treated in the way of mensuration is treated mathematically. Now, in the discourse of ordinary life and ordinary men, many things are called quantities which we cannot or do not measure. This is the case in the instances already given of the affections of the mind, pleasure, pain, beauty, wisdom, honour, &c. We do not say that they are incapable of measure; but we have not yet been able to measure them, nor do we think of measuring them when we speak rationally and usefully about them. We therefore do not consider them mathematically; nor can we introduce mathematical precision into our discussions of these subjects till we can, and actually do, measure them. Persons who are precise in their expression will even avoid such phrases on these subjects as suppose, or strictly express, such measurement. We should be much embarrassed how to answer the question, How much pain does the toothache give you just now; and how much is it easier since yesterday? Yet the answer (if we had a measure) would be as easy as to the question, How many guineas did you win at cards? or how much land have you bought? Nay, though we say familiarly, "I know well how much such a misfortune would affect you," and are understood when we say it, it would be awkward language to say, "I know well the quantity of your grief." It is in vain, therefore, to expect mathematical precision in our discourse or conceptions of quantities in the most abstracted sense. Such precision is confined to quantity which may be and is measured (A). It is only

Quantity.

trifling

(A) To talk intelligibly of the quantity of a pain, we should have some standard by which to measure it; some known degree of it so well ascertained, that all men, when talking of it, should mean the same thing.—And we should be able to compare other degrees of pain with this, so as to perceive distinctly, not only whether they exceed or fall short of it, but also how much, or in what proportion; whether by an half, or a fifth, or a tenth. *Reid.*

Quantity.

trifling with the imagination when we employ mathematical language on subjects which have not this property.

It will therefore be of some service in science to discriminate quantities in this view; to point out what are susceptible of measure, and what are not.

6
Measuring
explained.

What is measuring? It is one of these two things: It is either finding out some known magnitude of the thing measured, which we can demonstrate to be equal to it; or to find a known magnitude of it, which being taken so many times shall be equal to it. The geometer measures the contents of a parabolic space when he exhibits a parallelogram of known dimensions, and demonstrates that this parallelogram is equal to the parabolic space. In like manner, he measures the solid contents of an infinitely extended hyperbolic spindle, when he exhibits a cone of known dimensions, and demonstrates that three of these cones are equal to the spindle.

In this process it will be found that he actually subdivides the quantity to be measured into parts of which it consists, and states these parts as actually making up the quantity, specifying each, and assigning its boundaries. He goes on with it, piece by piece, demonstrating the respective equalities as he goes along, till he has exhausted the figure, or considered all its parts.—

When he measures by means of a submultiple, as when he shows the surface of a sphere to be equal to four of its great circles, he stops, after having demonstrated the equality of one of these circles to one part of the surface: then he demonstrates that there are other three parts, each of which is precisely equal to the one he has minutely considered. In this part of the process he expressly assigns the whole surface into its distinct portions, of which he demonstrates the equality.

But there is another kind of geometrical measurement which proceeds on a very different principle. The geometer conceives a certain individual portion of his figure, whether line, angle, surface, or solid, as known in respect to its dimensions. He conceives this to be lifted from its place, and again laid down on the adjoining part of the figure, and that it is equal to the part which it now covers; and therefore that this part together with the first is double of the first: he lifts it again, and lays it down on the next adjoining part, and affirms that this, added to the two former, make up a quantity triple of the first. He goes on in this way, making similar inferences, till he can demonstrate that he has in this manner covered the whole figure by twenty applications, and that his moveable figure will cover no more; and he affirms that the figure is twenty times the part employed.

7
Euclid's
fourth pro-
position.

This mode is precisely similar to the manner of practical measurement in common life: we apply a foot-rule successively to two lines, and find that 30 applications exhaust the one, while it requires 35 to exhaust the other. We say, therefore, that the one line is 30 and the other 35 feet long; and that these two lines are to each other in the ratio of 30 to 35. Having measured two shorter lines by a similar application of a stick of an inch long 30 times to the one and 35 times to the other, we say that the ratio of the two first lines is the same with that of the two last. Euclid has taken this method of demonstrating the fourth proposition of the first book of his celebrated elements.

But all this process is a fiction of the mind, and it is the fiction of an impossibility. It is even *inconceivable*,

that is, we cannot in imagination make this application of one figure to another; and we presume to say, that, if the elements of geometry cannot be demonstrated in some other way, the science has not that title to pure, abstract, and infallible knowledge, which is usually allowed it. We cannot *suppose* one of the triangles lifted and laid on the other, without supposing it something different from a triangle *in abstracto*. The *individuality* of such a triangle consists solely in its being in the precise place where it is, and in occupying *that* portion of space. If we could distinctly conceive otherwise, we should perceive that, when we have lifted the triangle from its place, and applied it to the other, it is gone from its former place, and that there is no longer a triangle *there*. This is inconceivable, and space has always been acknowledged to be immoveable. There is therefore some logical defect in Euclid's demonstration. We apprehend that he is labouring to demonstrate, or rather illustrate, a simple apprehension. This indeed is the utmost that can be done in any demonstration (see METAPHYSICS, n^o 82.): but the mode by which he guides the mind to the apprehension of the truth of his fourth proposition is not consistent either with pure mathematics or with the laws of corporeal nature. The real process, as laid down by him, seems to be this. We suppose something different from the abstract triangle; some *thing* that, in conjunction with other properties has the property of being triangular, with certain dimensions of two of its sides and the included angle. It has avowedly another property, not essential to, and not contained in, the abstract notion of a triangle, viz. mobility. We also suppose it permanent in shape and dimensions, or that although, *during* its motion, it does not occupy *the same space*, it continues and all its parts, to occupy *an equal space*. In short, our conception is very mixed, and does not perceptibly differ from our conception of a triangular piece of matter, where the triangle is not the subject, but an adjunct, a quality. And when we suppose the application made, we are not in fact supposing two abstract triangles to coincide. This we cannot do with any thing like distinctness; for our distinct conception now is, not that of two triangles coinciding, but of one triangle being now exactly occupied by that moveable thing which formerly occupied the other. In short, it is a vulgar measurement, restricted by suppositions which are inadmissible in all *actual* measurements: in the present universe, in which no moveable material thing is *known* to be permanent, either in shape or magnitude.

This is an undeniable consequence of the principle of universal gravitation, and the compressibility of every kind of tangible matter with which we are acquainted. Remove the brass rule but one inch from its place; its gravitation to the earth and to the rest of the universe is immediately changed, and its dimensions change of consequence. A change of temperature will produce a similar effect; and this is attended to and considered in all nice mensurations. We do the best we can to assure ourselves that our rule always occupies a sensibly equal space; and we must be contented with chances of error which we can neither perceive nor remove.

We might (were this a proper place) take notice of some other logical defects in the reasoning of this celebrated proposition: but they are beside our present purpose of explaining the different modes of mathematical

Quantity.

Quantity.

8

The characteristic notion of mensuration.

cal measurement, with the view of discovering that circumstance in which they all agree, and which (if the only one) must therefore be the characteristic of mensuration.

We think that the only circumstance in which all modes of mensuration agree, or the only notion that is found in them all, is, that the quantity is conceived as consisting of parts, distinguishable from each other, and separated by assignable boundaries; so that they are at once conceived separately and jointly. We venture to assert that no quantity is directly measured which we cannot conceive in this way, and that such quantities only are the immediate objects of mathematical contemplation, and should be distinguished by a generic name. Let them be called MATHEMATICAL QUANTITIES. EXTENSION, DURATION, NUMBER, and PROPORTION, have this characteristic, and they are the only quantities which have it. Any person will be convinced of the first assertion by attending to his own thoughts when contemplating these notions. He will find that he conceives every one of them as made up of its own parts, which are distinguishable from each other, and have assignable boundaries, and that it is only in consequence of involving this conception that they can be added to or subtracted from each other; that they can be multiplied, divided, and conceived in any proportion to each other.

He may perhaps find considerable difficulty in acquiring perfectly distinct notions of the mensurability, and the accuracy of the modes of mensuration. He will find that the way in which he measures duration is very similar to that in which he measures space or extension. He does not know, or does not attend to, any thing which hinders the brass foot-rule in his hand from continuing to occupy equal spaces during his use of it, in measuring the distance of two bodies. In like manner he selects an event which nature or art can repeat continually, and in which the circumstances which contribute to its accomplishment are invariably the same, or their variations and their effects are insensible. He concludes that it will always occupy an equal portion of time for its accomplishment, or always last an equal time. Then, observing that, during the event whose duration he wishes to measure, this standard event is accomplished $29\frac{1}{2}$ times, and that it is repeated $365\frac{1}{2}$ times during the accomplishment of another event, he affirms that the durations of these are in the ratio of $29\frac{1}{2}$ to $365\frac{1}{2}$. It is thus (and with the same logical defect as in the measuring a line by a brass rod) that the astronomer measures the celestial revolutions by means of the rotation of the earth round its axis, or by the vibrations of a pendulum.

We are indebted for most of the preceding observations to Dr Reid, the celebrated author of the Inquiry into the Human Mind on the Principles of Common Sense, and of the Essays on the intellectual and active powers of Man. He has published a dissertation on this subject in the 45th volume of the Philosophical Transactions, n^o 489, which we recommend to our philosophical readers as a performance eminent for precision and acuteness. If we presume to differ from him in any trivial circumstance, it is with that deference and respect which is due to his talents and his worth.

Dr Reid justly observes, that as nothing has proportion which has not either extension, duration, or num-

ber, the characters of mathematical quantity may be restricted to these three. He calls them PROPER quantities, and all others he calls IMPROPER. We believe that, in the utmost precision of the English language, this denomination is very apposite, and that the word *quantity*, derived from *quantum*, always supposes measurement: But the word is frequently used in cases where its original is not kept in view, and we use other words as synonymous with it, when all mensuration, whether possible or not, is out of our thoughts. According to practice, therefore, the *jus et norma loquendi*, there seems to be no impropriety in giving this name, in our language at least, to whatever can be conceived as great or little. There is no impropriety in saying that the pain occasioned by the stone is greater than that of the toothache; and when we search for the category to which the assertion may be referred, we cannot find any other than quantity. We may be allowed therefore to say, with almost all scientific men, that every thing is conceivable in respect of quantity which we can think or speak of as greater and less; and that this notion is the characteristic of quantity as a genus, while measurableness is the characteristic of mathematical quantity as a species.

But do we not measure many quantities, and consider them mathematically, which have not this characteristic of being made up of their own distinguishable parts? What else is the employment of the mechanician, when speaking of velocities, forces, attractions, repulsions, magnetic influence, chemical affinity, &c. &c.? Are not these mathematical sciences? And if the precision and certainty of mathematics arise from the nature of their specific object, are not all the claims of the mechanician and physical astronomer ill-founded pretensions? These questions require and deserve a serious answer.

It is most certain that we consider the notions which are expressed by these terms velocity, force, density, and the like, as susceptible of measure, and we consider them mathematically.

Some of these terms are nothing but names for relations of measurable quantity, and only require a little reflection to show themselves such. VELOCITY is one of these. It is only a name expressing a relation between the space described by a moving body and the time which elapses during its description. Certain moderate rates of motion are familiar to us. What greatly exceeds this, such as the flight of a bird when compared with our walking, excites our attention, and this excess gets a name. A motion not so rapid as we are familiar with, or as we wish, also gets a name; because in this the excess or defect may interest us. We wish for the flight of the hawk; we chide the tardy pace of our messenger: but it is scientific curiosity which first considers this relation as a *separate* object of contemplation, and the philosopher must have a name for it. He has not formed a new one, but makes use of a word of common language, whose natural meaning is the combination of a great space with a short time. Having once appropriated it, in his scientific vocabulary, to this very general use, it loses with him its true signification. Tardity would have done just as well, though its true meaning is diametrically opposite; and there is no greater impropriety in saying the tardity of a cannon bullet than in saying the velocity of the hour-hand of a watch.

Velocity

Quantity.

10

Other quantities that cannot be considered mathematically.

11

Velocity, force, density, how measured.

9

Characters of mathematical quantity.

Quantity. Velocity is a quality or affection of motion, the notion of which includes the notions of space and duration (two mathematical quantities), and no other. It does not therefore express a mathematical quantity itself, but a relation, a combination of two mathematical quantities of different kinds; and as it is measurable in the quantities so combined, its measure must be a unit of its own kind, that is, an unit of space *as combined* with an unit of time.

DENSITY is another word of the same kind, expressing a combination of space with number. *Dense arbores* means trees standing at a small distance from each other; and the word is used in the same sense when we say that quicksilver is denser than water. The expression always suggests to the reflecting mind the notions of particles and their distances. We are indeed so habituated to complicated views of things, that we can see remote connections with astonishing rapidity; and a very few circumstances are sufficient for leading forward the mind in a train of investigation. Common discourse is a most wonderful instance of this. It is in this way that we say, that we found by weighing them that inflammable air had not the sixth part of the density of common air. Supposing all matter to consist of equal atoms equally heavy, and knowing that the weight of a bladder of air is the sum of the weights of all the atoms, and also knowing that the *vicinity* of the atoms is in a certain proportion of the *number* contained in a given bulk, we affirm that common air is more than six times denser than inflammable air; but this rapid decision is entirely the effect of habit, which makes us familiar with certain groups of conceptions, and we instantaneously distinguish them from others, and thus think and discourse rationally. The Latin language employs the word *frequens* to express both the combination of space and number, and that of time and number.

There are perhaps a few more words which express combinations of mathematical quantities of different kinds; and the corresponding ideas or notions are therefore proper and immediate subjects of mathematical discussion: But there are many words which are expressive of things, or at least of notions, to which this way of considering them will not apply. All those affections or qualities of external bodies, by which they are conceived to act on each other, are of this kind: IMPULSIVE FORCE, WEIGHT, CENTRIPETAL AND CENTRIFUGAL FORCE, MAGNETICAL, ELECTRICAL, CHEMICAL ATTRACTIONS AND REPULSIONS; in short, all that we consider as the immediate causes of natural phenomena. These we familiarly measure, and consider mathematically.

12
Forces measured in the phenomena.

What was said on this subject in the article PHYSICS will give us clear conceptions of this process of the mind. These forces or causes are not immediate objects of contemplation, and are known only *by* and *in* the phenomena which we consider as their effects. The phenomenon is not only the indication of the agency of any cause, and the characteristic of its kind, but the measure of its degree. The necessary circumstances in this *train of human thought* are, 1st, The notion of the force as something susceptible of augmentation and diminution. 2d, The notion of an inseparable connection of the force with the effect produced, and of every degree of the one with a corresponding degree of the other. From these is formed the notion that the phenomenon

1

or effect is the proper measure of the force or cause. *Quantity.* All this is strictly logical.

But when we are considering these subjects mathematically, the immediate objects of our contemplation are not the forces which we are thus treating. It is not their relations which we perceive, and which we combine with such complication of circumstances and certainty of inference as are unknown in all other sciences: by no means; they are the phenomena only, which are subjects of purely mathematical discussion. They are motions, which involve only the notions of space and time; and when we have finished an accurate mathematical investigation, and make our affirmation concerning the forces, we are certain of its truth, because we *suppose* the forces to have the proportions and relations, and no other, which we observe in the phenomena. Thus, after having demonstrated, by the geometrical comparison of the lines and angles and surfaces of an ellipse, that the momentary deflection of the moon from the tangent of her orbit is the 3600th part of the simultaneous deflection of a stone from the tangent of its parabolic path, Newton affirms, that the force by which a particle of the moon is retained in her orbit is the 3600th part of the weight of a particle of the stone; and having farther shown, from fact and observation, that these momentary deflections are inversely as the squares of the distances from the centre of the earth, he affirms, that all this is produced by a force which varies its intensity in this manner.

Now all this investigation proceeds on the two suppositions mentioned above, and the measures of the forces are in fact the measures of the phenomena. The whole of physical astronomy, and indeed the whole of mechanical philosophy, might be taught and understood, without ever introducing the word force, or the notion which it is supposed to express: for our mathematical reasonings are really about the phenomena, which are subjects purely mathematical.

The precision, therefore, that we presume to affirm to attend these investigations, arises entirely from the measurable nature of the quantities which are the real objects of our contemplation, and the suitableness and propriety of the measures which we adopt in our comparisons.

Since, then, the phenomena are the *immediate* subjects of our discussion, and the operating powers are only inferences from the phenomena considered as effects, the quantity ascribed to them must also be an inference from the quantity of the effect, or of some circumstance in the effect. The measure, therefore, of the cause, or natural power or force, cannot be one of its own parts; for the whole and the part are equally unperceived by us. Our measure, therefore, must be a measure of some interesting part, or of the only interesting part of the phenomenon. It is therefore in a manner arbitrary, and depends chiefly on the interest we take in the phenomenon. It must, however, be settled with precision, so that all men in using it may mean the same thing. It must be settled, therefore, by the description of that part or circumstance of the phenomenon which is characteristic of the natural power. This description is the *definition* of the measure.

Thus Newton assumes as his measure of the centripetal force, the momentary deviation from uniform rectilineal motion. Others, and sometimes Newton himself,

13
Measures of centripetal force.

Quantity.

himself, assumes the momentary change of velocity, which again is measured by *twice this deviation*. These measures, being thus selected, are always proper in a mathematical sense; and if strictly adhered to, can never lead us into any paralogism. They may, however, be physically wrong: there may not be that indissoluble connection between the phenomenon and the supposed cause. But this is no mathematical error, nor does it invalidate any of our mathematical inferences: it only makes them useless for explaining the phenomenon by the principles which we adopted; but it prepares a modification of the phenomenon for some more fortunate application of physical principles.

14
Requisites
of such
measures.

All that can be desired in the definitions or descriptions of these measures is, that they may not deviate from the ordinary use of the terms, because this would always create confusion, and occasion mistakes. Dr Reid has given an example of an impropriety of this kind, which has been the subject of much debate among the writers on natural philosophy. We mean the measure of the force inherent in a body in motion. Descartes, and all the writers of his time, assumed the velocity produced in a body as the measure of the force which produces it; and observing that a body, in consequence of its being in motion, produces changes in the state or motion of other bodies, and that these changes are in the proportion of the velocity of the changing body, they asserted that there is in a moving body a *VIS INSITA*, an *INHERENT FORCE*, and that this is proportional to its velocity; saying that its force is twice or thrice as great, when it moves twice or thrice as fast at one time as at another. But Leibnitz observed, that a body which moves twice as fast, rises four times as high, against the uniform action of gravity; that it penetrates four times as deep into a piece of uniform clay; that it bends four times as many springs, or a spring four times as strong, to the same degree; and produces a great many effects which are four times greater than those produced by a body which has half the initial velocity. If the velocity be triple, quadruple, &c. the effects are nine times, 16 times, &c. greater; and, in short, are proportional, not to the velocity, but to its square. This observation had been made before by Dr Hooke, who has enumerated a prodigious variety of important cases in which this proportion of effect is observed. Leibnitz, therefore, affirmed, that the force inherent in a moving body is proportional to the square of the velocity.

15
Controversy
between
the Cartesi-
ans and
Leibnitz-
ians on this
subject.

It is evident that a body, moving with the same velocity, has the same inherent force, whether this be employed to move another body, to bend springs, to rise in opposition to gravity, or to penetrate a mass of soft matter. Therefore these measures, which are so widely different, while each is agreeable to a numerous class of facts, are not measures of this something inherent in the moving body which we call its force, but are the measures of its exertions when modified according to the circumstances of the case; or, to speak still more cautiously and securely, they are the measures of certain classes of phenomena consequent on the action of a moving body. It is in vain, therefore, to attempt to support either of them by a demonstration. The measure itself is nothing but a definition. The Cartesian calls that a double force which produces a double velocity in the body on which it acts. The Leibnitzian calls

that a quadruple force which makes a quadruple penetration. The reasonings of both in the demonstration of a proposition in dynamics may be the same, as also the result, though expressed in different numbers.

But the two measures are far from being equally proper: for the Leibnitzian measure obliges us to do continual violence to the common use of words. When two bodies moving in opposite directions meet, strike each other, and stop, all men will say that their forces are equal, because they have the best test of equality which we can devise. Or when two bodies in motion strike the parts of a machine, such as the opposite arms of a lever, and are thus brought completely to rest, we and all men will pronounce their mutual energies by the intervention of the machine to be equal. Now, in all these cases, it is well known that a perfect equality is found in the products of the quantities of matter and velocity. Thus a ball of two pounds, moving with the velocity of four feet in a second, will stop a ball of eight pounds moving with the velocity of one foot per second. But the followers of Leibnitz say, that the force of the first ball is four times that of the second.

All parties are agreed in calling gravity a uniform or invariable accelerating force; and the definition which they give of such a force is, that it always produces the same acceleration, that is, equal accelerations in equal times, and *therefore* produces augmentations of velocity proportionable to the times in which they are produced. The only effect ascribed to this force, and consequently the only thing which indicates, characterises, and measures it, is the augmentation of velocity. What is this velocity, considered not merely as a mathematical term, but as a phenomenon, as an event, a production by the operation of a natural cause? It cannot be conceived any other way than as a *determination* to move on forever at a certain rate, if nothing shall change it. We cannot conceive this very clearly. We feel ourselves forced to animate, as it were, the body, and give it not only a will and intention to move in this manner, but a real exertion of some faculty in consequence of this determination of mind. We are conscious of such a train of operations in ourselves; and the last step of this train is the exertion or energy of some natural *faculty*, which we, in the utmost propriety of language, call force. By such analogical conception, we suppose a something, an energy, inherent in the moving body; and its only office is the production and continuation of this motion, as in our own case. Scientific curiosity was among our latest wants, and language was formed long before its appearance: as we formed analogical conceptions, we contented ourselves with the words already familiar to us, and to this something we gave the name Force, which expressed that energy in ourselves which bears some resemblance (in office at least) to the determination of a body to move on at a certain rate. This sort of allegory pervades the whole of our conceptions of natural operations, and we can hardly think or speak of any operation without a language, which supposes the animation of matter. And, in the present case, there are so many points of resemblance between the effects of our exertions and the operations of nature, that the language is most expressive, and has the strongest appearance of propriety. By exerting our force, we not only move and keep in motion, but we move other bodies. Just so a ball not only moves,

Quantity.

Quantity. but puts other bodies in motion, or penetrates them, &c.—This is the origin of that conception which so forcibly obtrudes itself into our thoughts, that there is inherent in a moving body a force by which it produces changes in other bodies. No such thing appears in the same body if it be not in motion. We therefore conclude, that it is the production of the moving force, whatever that has been. If so, it must be conceived as proportional to its producing cause. Now this force, thus produced or exerted in the moving body, is only another way of conceiving that determination which we call velocity, when it is conceived as a natural event. We can form no other notion of it. The *vis insita*, the determination to move at a certain rate, and the velocity, are one and the same thing, considered in different relations.

16
Vis insita.

Therefore the *vis insita corpori moventi*, the determination to move at a certain rate, and the velocity, should have one and the same measure, or any one of them may be taken for the measure of the other. The velocity being an object of perception, is therefore a proper measure of the inherent force; and the propriety is more evident by the perfect agreement of this use of the words with common language. For we conceive and express the action of gravity as uniform, when we think and say that its effects are proportional to the times of its action. Now all agree, that the velocity produced by gravity is proportional to the time of its action. And thus the measure of force, in reference to its producing cause, perfectly agrees with its measure, independent of this consideration.

But this agreement is totally lost in the Leibnitzian doctrine; for the body which has fallen four times as far, and has sustained the action of gravity twice as long, is said to have four times the force.

17
Conser-
vatio
virium vi-
varum.

* Micro-
graphia, vis
restitutiva,
&c. in his
Posthu-
mous
Works,

The quaintness and continual paradox of expression which this measure of inherent force leads us into, would have quickly exploded it, had it not been that its chief abettors were leagued in a keen and acrimonious warfare with the British mathematicians who supported the claim of Sir Isaac Newton to the invention of fluxions. They rejoiced to find in the elegant writings of Huyghens a physical principle of great extent, such as this is, which could be set in comparison with some of the wonderful discoveries in Newton's Principia. The fact, that in the mutual actions of bodies on each other the products of the masses and the squares of the velocities remain always the same (which they call the *conservatio virium vivarum*), is of almost universal extent; and the knowledge of it enabled them to give ready and elegant solutions of the most abstruse and intricate problems, by which they acquired a great and deserved celebrity. Dr Robert Hooke, whose observation hardly any thing escaped, was the first (long before Huyghens) who remarked*, that in all the cases of the gradual production and extinction of motion, the sensible phenomenon is proportional to the square of the produced or extinguished velocity.

John Bernoulli brought all these facts together, and systematized them according to the principle advanced by Huyghens in his treatise on the centre of oscillation. He and Daniel Bernoulli gave most beautiful specimens of the prodigious use of this principle for the solution of difficult physical problems in their dissertations on the motion and impulse of fluids, and on the commu-

nication of motion. It was however very early objected to them (we think by Marquis Poleni), that in the collision of bodies perfectly hard there was no such *conservatio virium vivarum*; and that, in this case, the forces must be acknowledged to be proportional to the velocities. The objections were unanswerable.—But John Bernoulli evaded their force, by affirming that there were and could be no bodies perfectly hard. This was the origin of another celebrated doctrine, on which Leibnitz greatly plumed himself, the Law of Continuity, viz that nothing is observed to change abruptly, or *per saltum*. But no one will pretend to say that a perfectly hard body is an inconceivable thing; on the contrary, all will allow that softness and compressibility are adjunct ideas, and not in the least necessary to the conception of a particle of matter, nay totally incompatible with our notion of an ultimate atom.

Quantity.
18
Law of
continuity.

Sir Isaac Newton never could be provoked to engage in this dispute. He always considered it as a wilful abuse of words, and unworthy of his attention. He guarded against all possibility of cavil, by giving the most precise and perspicuous definitions of those measures of forces, and all other quantities which he had occasion to consider, and by carefully adhering to them. And in one proposition of about 20 lines, viz. the 39th of the 1st book of the Principia, he explained every phenomenon adduced in support of the Leibnitzian doctrine, showing them to be immediate consequences of the action of a force measured by the velocity which it produces or extinguishes. There it appears that the heights to which bodies will rise in opposition to the uniform action of gravity are as the squares of the initial velocities: So are the depths to which they will penetrate uniformly resisting matter: So is the number of equal springs which they will bend to the same degree, &c. &c. &c. We have had frequent occasion to mention this proposition as the most extensively useful of all Newton's discoveries. It is this which gives the immediate application of mechanical principles to the explanation of natural phenomena. It is incessantly employed in every problem by the very persons who hold by the other measure of forces, although such conduct is virtually giving up that measure. They all adopt, in every investigation, the two theorems $ft = v$, and $fs = vv$; both of which suppose an accelerating force f proportional to the velocity v which it produces by its uniform action during the time t , and the theorem $ffs = v^2$ is the 39th 1. Princip.

Great supe-
riority of
Newton.

and is the *conservatio virium vivarum*.

This famous dispute (the only one in the circle of mathematical science) has led us somewhat aside. But we have little more to remark with respect to measurable quantity. We cannot say what varieties of quantity are susceptible of strict measure, or that it is impossible to give accurate measures of every thing susceptible of augmentation and diminution. We affirm, however, with confidence, that pain, pleasure, joy, &c. are not made up of their own parts, which can be contemplated separately; but they may chance to be associated by nature with something that is measurable; and we may one day be able to assign their degrees with as much precision as we now ascertain the degrees of warmth by the expansion of the fluid in the thermometer. There is one sense in which they may all be

be

Quantity
Quarrels.

be measured, viz. numerically, as Newton measures density, *vis motrix*, &c. We can conceive the pain of each of a dozen men to be the same. Then it is evident that the pain of eight of these men is to that of the remaining four as two to one; but from such enumeration we do not foresee any benefit likely to arise.

QUANTITY, in grammar, an affection of a syllable, whereby its measure, or the time wherein it is pronounced, is ascertained; or that which determines the syllable to be long or short.

Quantity is also the object of prosody, and distinguishes verse from prose; and the economy and arrangement of quantities, that is, the distribution of long and short syllables, makes what we call the *number*. See POETRY, Part III.

The quantities are used to be distinguished, among grammarians, by the characters, short, as *për*; and—, long, as *rôs*. There is also a common, variable, or dubious quantity; that is, syllables that are one time taken for short ones, and at another time for long ones; as the first syllable in *Atlas*, *patres*, &c.

QUARANTINE, is a trial which ships must undergo when suspected of a pestilential infection. In England it may be ordered by the king, with advice of the privy-council, at such times, and under such regulations, as he judges proper. Ships ordered on quarantine must repair to the place appointed, and must continue there during the time prescribed (generally six weeks); and must have no intercourse with the shore, except for necessary provisions, which are conveyed with every possible precaution. When the time is expired, and the goods opened and exposed to the air as directed, if there be no appearance of infection they are admitted to port.

Ships infected with the pestilence must proceed to St Helen's Pool in the Scilly islands, and give notice of their situation to the customhouse officers, and wait till the king's pleasure be known.

Persons giving false information to avoid performing quarantine, or refusing to go to the place appointed, or escaping, also officers appointed to see quarantine performed, deserting their office, neglecting their duty, or giving a false certificate, suffer death as felons.

Goods from Turkey, or the Levant, may not be landed without license from the king, or certificate that they have been landed and aired at some foreign port. See PLAGUE.

QUARLES (Francis), the son of James Quarles clerk to the board of green cloth and purveyor to queen Elizabeth, was born in 1592. He was educated at Cambridge; became a member of Lincoln's inn; and was for some time cup bearer to the Queen of Bohemia, and chronologer to the city of London. It was probably on the ruin of her affairs that he went to Ireland as secretary to archbishop Usher; but the troubles in that kingdom forcing him to return, and not finding affairs more at peace in England, some disquiets he met with were thought to have hastened his death, which happened in 1644. His works both in prose and verse are numerous, and were formerly in great esteem, particularly his *Divine Emblems*: but the obsolete quaintness of his style has caused them to fall into neglect, excepting among particular classes of readers.

"The memory of Quarles, says a late author, has been branded with more than common abuse, and he seems to have been censured merely from the want of being read

If his poetry failed to gain him friends and readers, his piety should at least have secured him peace and goodwill. He too often no doubt, mistook the enthusiasm of devotion for the inspiration of fancy; to mix the waters of Jordan and Helicon in the same cup, was reserved for the hand of Milton; and for him, and him only, to find the bays of Mount Olivet equally verdant with those of Parnassus. Yet, as the effusions of a real poetical mind, however thwarted by untowardness of subject, will be seldom rendered totally abortive, we find in Quarles original imagery, striking sentiment, fertility of expression, and happy combinations; together with a compression of style that merits the observation of the writers of verse. Gross deficiencies of judgment, and the infelicity of his subjects, concurred in ruining him. Perhaps no circumstance whatever can give a more complete idea of Quarles's degradation than a late edition of his emblems; the following passage is extracted from the preface: "Mr Francis Quarles, the author of the Emblems that go under his name, was a man of the most exemplary piety, and had a deep insight into the mysteries of our holy religion. But, for all that, the book itself is written in so old a language, that many parts of it are scarce intelligible in the present age; many of his phrases are so affected, that no person, who has any taste for reading, can peruse them with the least degree of pleasure; many of his expressions, are harsh, and sometimes whole lines are included in a parenthesis, by which the mind of the reader is diverted from the principal object. His Latin mottos under each cut can be of no service to an ordinary reader, because he cannot understand them. In order, therefore, to accommodate the public with an edition of Quarles's Emblems properly modernised, this work was undertaken." Such an exhibition of Quarles is chaining Columbus to an oar, or making John Duke of Marlborough a train-band corporal."

QUARRIES, a name commonly given to a most extraordinary cavern under the city of Paris, the existence of which is known to few even of the inhabitants, and many of those who have heard of it consider the whole as an idle story. Mr Thomas White, however, member of the Royal Medical Society of Edinburgh, &c. who visited it in 1784, puts the matter beyond a doubt; having, with many others, obtained leave (which is very cautiously granted) to inspect it, having guides and torches with them. He gives the following account of it in the second volume of the *Manchester Transactions*. "At the entrance by the *Observatoire Royal*, the path is narrow for a considerable way; but soon we entered large and spacious streets, all marked with names, the same as in the city; different advertisements and bills were found, as we proceeded, posted on the walls, so that it had every appearance of a large town swallowed up in the earth.

"The general height of the roof is about 9 or 10 feet; but in some parts not less than 30 and even 40. In many places there is a liquor continually dropping from it, which congeals immediately, and forms a species of transparent stone, but not so fine and clear as rock crystal. As we continued our peregrination, we thought ourselves in no small danger from the roof, which we found but indifferently propped in some places with wood much decayed. Under the houses, and many of the streets, however, it seemed to be tolerably secured by immense stones set in mortar; in other parts, where

Ancient Eng-
lish Poetry.

Quarries.

there are only fields or gardens above, it was totally unsupported for a considerable space, the roof being perfectly level, or a plane piece of rock. After traversing about two miles, we again descended about 20 steps, and here found some workmen in a very cold and damp place, propping up a most dangerous part, which they were fearful would give way every moment. The path here is not more than three feet in width, and the roof so low, that we were obliged to stoop considerably.

"On walking some little distance farther, we entered into a kind of saloon cut out of the rock, and said to be exactly under the *Eglise de St Jacques*. This was illuminated with great taste, occasioned an agreeable surprise, and made us all ample amends for the danger and difficulty we had just before gone through. At one end was a representation in miniature of some of the principal forts in the Indies, with the fortifications, drawbridges, &c. Cannons were planted with a couple of soldiers to each ready to fire. Centinels were placed in different parts of the garrison, particularly before the governor's house; and a regiment of armed men was drawn up in another place with their general in the front. The whole was made up of a kind of clay which the place affords, was ingeniously contrived, and the light that was thrown upon it gave it a very pretty effect.

"On the other side of this hall was a long table set out with cold tongues, bread, and butter, and some of the best Burgundy I ever drank. Now every thing was hilarity and mirth; our fears were entirely dispelled, and the danger we dreaded the moment before was now no longer thought of. In short, we were all in good spirits again, and proceeded on our journey about two miles farther, when our guides judged it prudent for us to ascend, as we were then got to the steps which lead up to the town. We here found ourselves safe at the *Val de Grace*, near to the English Benedictine convent, without the least accident having happened to any one of the party. We imagined we had walked about two French leagues, and were absent from the surface of the earth betwixt four and five hours.

"There were formerly several openings into the quarries, but the two I have mentioned, viz. the *Observatory* and the *Val de Grace*, are, I believe, the only ones left; and these the inspectors keep constantly locked, and rarely open them, except to strangers particularly introduced, and to workmen who are always employed in some part by the king. The police thought it a necessary precaution to secure all the entrances into this cavern, from its having been formerly inhabited by a famous gang of robbers, who infested the country for many miles round the city of Paris.

"As to the origin of this quarry, I could not, on the strictest inquiry, learn any thing satisfactory; and the only account I know published is the following contained in the *Tableaux de Paris, nouvelle edition, tom premier, chapitre 5me, page 12me*.

"For the first building of Paris it was necessary to get the stone in the environs; and the consumption of it was very considerable. As Paris was enlarged, the suburbs were insensibly built on the ancient quarries, so that all that you see without is essentially wanting in the earth for the foundation of the city: hence proceed the frightful cavities which are at this time

found under the houses in several quarters. They stand upon abysses. It would not require a very violent shock to throw back the stones to the place from whence they have been raised with so much difficulty. Eight men being swallowed up in a gulph 150 feet deep, and some other less known accidents, excited at length the vigilance of the police and the government, and, in fact, the buildings of several quarters have been privately propped up; and by this means a support given to these obscure subterraneous places which they before wanted.

"All the suburbs of St James's, Harp-street, and even the street of Tournon, stand upon the ancient quarries; and pillars have been erected to support the weight of the houses. What a subject for reflections, in considering this great city formed and supported by means absolutely contrary! These towers, these steeples, the arched roofs of these temples, are so many signs to tell the eye that what we now see in the air is wanting under our feet."

QUARRY, a place under ground, out of which are got marble, freestone, slate, limestone, or other matters proper for building. See STRATA.

Some limestone quarries in Fife are highly worthy the attention of the curious, on account of an amazing mixture of sea-bodies found in them. One of this kind was opened about the year 1759, at a farm called *Enderteel*, in the neighbourhood of Kirkaldy, belonging to General St Clair.

The flakes of the stone, which are of unequal thickness, most of them from eight to ten inches, lie horizontally, dipping towards the sea. Each of these flakes, when broken, presents to our view an amazing collection of petrified sea bodies, as the bones of fishes, stalks of sea-weed, vast quantities of shells, such as are commonly found on those coasts, besides several others of very uncommon figures. In some places the shells are so numerous, that little else is to be seen but prodigious clusters or concretions of them. In the uppermost stratum the shells are so entire, that the outer crust or plate may be scraped off with the finger; and the stalks of the sea-weed have a darkish colour, not that glossy whiteness which they have in the heart of the quarry. The smallest rays or veins of the shells are deeply indented on the stone, like the impression of a seal upon wax. In short, no spot at the bottom of the ocean could exhibit a greater quantity of sea-bodies than are to be found in this solid rock; for we have the skeletons of several fishes, the *antennæ* or feelers of lobsters, the roots and stalks of sea-weeds, with the very *capsule* which contain the seed. The place where all these curiosities are found is on an eminence about an English mile from the sea; and as the ground is pretty steep the whole way, it may be 200 feet higher at least.

There are two or three things to be remarked here. 1. That among all the bodies we have mentioned, there are none but what are specifically heavier than water. This holds so constantly true, that the sea-weed, which floats in water when the plant is entire, has been stripped of the broad leaves, which make it buoyant, before it has been lodged here. 2. The shells have been all empty; for the double ones, as those of the flat kind, are always found single, or with one side only. 3. The rock seems to have been gradually deserted.

Quarry.

Quarry
Quarter.

ferted by the sea, and for a long time, washed with the tides; for the upper surface is all eaten, and hollowed in many places like an honey-comb, just as we observe in flat rocks exposed every tide, to the access and recess of the waters. See the article SEA.

QUARRY, or *Quarril*, among glaziers, a pane of glass cut in a diamond form.

Quarries are of two kinds, square and long; each of which are of different sizes, expressed by the number of the pieces that make a foot of glass, viz. eighths, tenths, eightieths, and twentieths: but all the sizes are cut to the same angles, the acute angle in the square quarrels being $77^{\circ} 19'$, and $67^{\circ} 21'$ in the long ones.

QUARRY, among hunters, is sometimes used for a part of the entrails of the beast taken, given by way of reward to the hounds.

QUARRY, in falconry, is the game which the hawk is in pursuit of, or has killed.

QUARTAN, a measure containing the fourth part of some other measure.

QUARTAN, a species of intermitting fever. See MEDICINE, n^o 153, 158, and 159.

QUARTATION, is an operation by which the quantity of one thing is made equal to a fourth part of the quantity of another thing. Thus when gold allayed with silver is to be parted, we are obliged to facilitate the action of the aquafortis, by reducing the quantity of the former of these metals to one fourth part of the whole mass; which is done by sufficiently increasing the quantity of the silver, if it be necessary. This operation is called *quartation*, and is preparatory to the parting; and even many authors extend this name to the operation of parting. See the article PARTING.

QUARTER, the fourth part of any thing, the fractional expression for which is $\frac{1}{4}$.

QUARTER, in weights, is generally used for the fourth part of an hundred weight avoirdupois, or 28 lb.

Used as the name of a dry measure, *quarter* is the fourth part of a ton in weight, or eight bushels.

QUARTER, a term in the manege. To work from quarter to quarter, is to ride a horse three times in upon the first of the four lines of a square; then changing your hand, to ride him three times upon the second: and so to the third and fourth; always changing hands, and observing the same order.

QUARTERS, with respect to the parts of a horse, is used in various senses: thus the shoulders and fore-legs are called the *fore-quarters*, and the hips and hinder-legs the *hind-quarters*. The *quarters* of a horse's foot are the sides of the coffin, comprehending between the toe and the heel: the *inner* quarters are those opposite to one another, facing from one foot to the other; and these are always weaker than the *outside* quarters, which lie on the external sides of the coffin. *False quarters*, are a cleft in the horn of a horse's hoof, extending from the coronet to the shoe. A horse is said to be *quarter-cast*, when for any disorder in the coffin we are obliged to cut one of the quarters of the hoof.

QUARTER, in astronomy, the fourth part of the moon's period: thus, from the new moon to the quadrature is the first quarter; from this to full moon, the second quarter, &c.

QUARTER, in heraldry, is applied to the parts or

members of the first division of a coat that is quartered, or divided into four quarters.

FRANC QUARTER, in heraldry, is a quarter single or alone; which is to possess one fourth part of the field. It makes one of the honourable ordinaries of a coat.

QUARTER of a ship, that part of the ship's side which lies towards the stern; or which is comprehended between the aftmost end of the main chains and the sides of the stern, where it is terminated by the quarter-pieces.

Although the lines by which the quarter and bow of a ship, with respect to her length, are only imaginary, yet experience appears sufficiently to have ascertained their limits: so that if we were to divide the ship's sides into five equal portions, the names of each space would be readily enough expressed. Thus the first, from the stern, would be the quarter; the second, abaft the midships; the third, the midships; the fourth, before the midships; and the fifth, the bow. Whether these divisions, which in reality are somewhat arbitrary, are altogether improper, may be readily discovered by referring to the mutual situation or approach of two adjacent vessels. The enemy boarded us on the larboard side! Whereabouts? Abaft the midships, before the midships, &c.

Plate CCCCXXVII. n^o 1. represents a geometrical elevation of a quarter of a 74 gun ship. A the keel, with *a* the false keel beneath it. B the stern-post. DD the quarter-gallery, with its ballustrades and windows. EE the quarter-pieces, which limit and form the outlines of the stern. F the taffarel, or upper pieces of the stern. FG the profile of the stern, with its galleries. H the gun-ports of the lower-deck; *h* the gun-ports of the upper and quarter-deck. I the after-part of the mizen-channel. K the wing-transom. KG the lower counter. LB the station of the deck-transom. LQ the after-part of the main-wale. DR the after-part of the channel-wale, parallel to the main-wale. SU the sheer-rail, parallel to both wales. T *t* the rudder. A *t* F the rake of the stern. P *i* *i* the drift-rails. TU the after-part of the load *water-line*; *k k l* the curve of the several decks corresponding to those represented in the head. See the article HEAD.

As the marks, by which vessels of different constructions are distinguished from each other, are generally more conspicuous on the stern or quarter than any other part, we have represented some of the quarters, which assume the most different shapes, and form the greatest contrast with each other. N^o 2. shows the stern and quarter of a Dutch frigate. N^o 3. the stern and quarter of a cat. N^o 4. is the stern and quarter of a common galley. N^o 5. exhibits the quarter of a first-rate galley, otherwise called a *galleasse*. N^o 6. the quarter of a Dutch dogger, or galliot. N^o 7. represents the stern and quarter of a sloop of war.

The quarters of all other ships have a near affinity to those above exhibited. Thus all ships of the line, and East-Indiamen, are formed with a quarter little differing from the principal figure in this plate. Xebecs have quarters nearly resembling those of galleasses, only somewhat higher. Hagboats and pinks approach the figure of *cats*, the former being a little broader in the stern, and the latter a little narrower; and the sterns and quarters of *cats* seem to be derived from those of fly-boats.

Quarter.

Quarter. boats. The sterns of Dutch doggers and galliots are indeed singular, and like those of no other modern vessel: they have nevertheless a great resemblance to the ships of the ancient Grecians, as represented in medals and other monuments of antiquity.

On the *QUARTER*, may be defined an arch of the horizon, contained between the line prolonged from the ship's stern and any distant object, as land, ships, &c. Thus if the ship's keel lies on an east and west line, the stern being westward, any distant object perceived on the north-west or south-west, is said to be on the larboard or starboard quarter.

QUARTER-Bill, a roll, or list, containing the different stations, to which all the officers and crew of the ship are quartered in the time of battle, and the names of all the persons appointed to those stations. See *QUARTERS*.

QUARTER-Master, is an officer, generally a lieutenant, whose principal business is to look after the quarters of the soldiers, their clothing, bread, ammunition, firing, &c. Every regiment of foot and artillery has a quarter-master, and every troop of horse one, who are only warrant-officers, except in the Blues.

QUARTER-Master-General, is a considerable officer in the army; and should be a man of great judgment and experience, and well skilled in geography. His duty is to mark the marches and encampments of an army: he should know the country perfectly well, with its rivers, plains, marshes, woods, mountains, defiles, passages, &c. even to the smallest brook. Prior to a march, he receives the order and route from the commanding general, and appoints a place for the quarter-masters of the army to meet him next morning, with whom he marches to the next camp; where being come, and having viewed the ground, he marks out to the regimental quarter-masters the ground allowed each regiment for their camp: he chooses the head-quarters, and appoints the villages for the generals of the army's quarters: he appoints a proper place for the encampment of the train of artillery: he conducts foraging parties, as likewise the troops to cover them against assaults, and has a share in regulating the winter-quarters and cantonments.

QUARTER-Netting, a sort of net-work, extended along the rails on the upper part of a ship's quarter. In a ship of war these are always double, being supported by iron cranes, placed at proper distances. The interval is sometimes filled with cork, or old sails; but chiefly with the hammocks of the sailors, so as to form a parapet to prevent the execution of the enemy's small arms in battle.

QUARTER Sessions, a general court held quarterly by the justices of peace of each county. This court is appointed by stat. 2. Hen. V. c. 4. to be in the first week after Michaelmas-day; the first week after the Epiphany; the first week after the close of Easter; and in the week after the translation of Saint Thomas a Becket, or the 7th of July. This court is held before two or more justices of the peace, one of whom must be of the *quorum*. The jurisdiction of this court by 34 Ed. III. c. 1. extends to the trying and determining of all felonies and trespasses whatsoever, though they seldom, if ever, try any greater offence than small fe-

lonies within the benefit of clergy, their commission providing, that if any case of difficulty arises, they shall not proceed to judgment, but in the presence of one of the justices of the courts of king's bench or common pleas, or one of the judges of assize. And therefore murderers and other capital felons are usually remitted for a more solemn trial to the assizes. They cannot also try any new-created offence, without express power given them by the statute which creates it. But there are many offences, and particular matters, which by particular statutes belong properly to this jurisdiction, and ought to be prosecuted in this court; as, the smaller misdemeanors against the public or commonwealth, not amounting to felony, and especially offences relating to the game, highways, alehouses, bastard children, the settlement and provision for the poor, vagrants, servants wages, apprentices, and popish recusants. Some of these are proceeded upon by indictment, and others in a summary way by motion and order thereupon; which order may, for the most part, unless guarded against by particular statutes, be removed into the court of king's bench, by writ of *certiorari facias*, and be there either quashed or confirmed. The records or rolls of the sessions are committed to the custody of a special officer, denominated the *custos rotulorum*. In most corporation towns there are quarter-sessions kept before justices of their own, within their respective limits, which have exactly the same authority as the general quarter-sessions of the county, except in very few instances: one of the most considerable of which is the matter of appeals from orders of removal of the poor, which, though they be from the orders of corporation justices, must be to the sessions of the county, by 8 and 9 Will. III. c. 30. In both corporations and counties at large, there is sometimes kept a special or petty session, by a few justices, for dispatching smaller business in the neighbourhood between the times of the general sessions, as for licensing alehouses, passing the accounts of parish-officers, and the like.

QUARTER-Staff, a long staff borne by foresters, park-keepers, &c. as a badge of their office, and occasionally used as a weapon.

QUARTERS, a name given at sea to the several stations where the officers and crew of a ship of war are posted in action. See *Naval Tactics*.

The number of men appointed to manage the artillery is always in proportion to the nature of the guns, and the number and condition of the ship's crew. They are, in general, as follow, when the ship is well manned, so as to fight both sides at once occasionally:

Pounder.	No. of men.	Pounder.	No. of men.
To a 42	- 15	To a 9	- 6
32	- 13	6	- 5
24	- 11	4	- 4
18	- 9	3	- 3
12	- 7		

This number, to which is often added a boy to bring powder to every gun, may be occasionally reduced, and the guns nevertheless well managed. The number of men appointed to the small arms, on board his majesty's ships and sloops of war, by order of the admiralty, are,

Rate

Quarters	Rate of the ship.	No. of men to the small arms.	Quartz.
1st	-	150	
2d	-	120	
3d of 80 guns	-	100	
— of 70 guns	-	80	
4th of 60 guns	-	70	
4th of 50 guns	-	60	
5th	-	50	
6th	-	40	
Sloops of war	-	30	

The lieutenants are usually stationed to command the different batteries, and direct their efforts against the enemy. The master superintends the movements of the ship, and whatever relates to the sails. The boatswain, and a sufficient number of men, is stationed to repair the damaged rigging; and the gunner and carpenter, wherever necessary, according to their respective offices.

The marines are generally quartered on the poop and fore-castle, or gang-way, under the direction of their officers; although, on some occasions, they assist at the great guns, particularly in distant cannonading.

QUARTERS, at a siege, the encampment upon one of the most principal passages round a place besieged, to prevent relief and convoys.

Head QUARTERS of an Army, the place where the commander in chief has his quarters. The quarters of generals of horse are, if possible, in villages behind the right and left wings, and the generals of foot are often in the same place: but the commander in chief should be near the centre of the army.

QUARTERS of Refreshment, the place or places where troops that have been much harassed are put to recover themselves during some part of the campaign.

Intrenched QUARTERS, a place fortified with a ditch and parapet to secure a body of troops.

Winter QUARTERS, sometimes means the space of time included between leaving the camp and taking the field; but more properly the places where the troops are quartered during the winter.

The first business, after the army is in winter-quarters, is to form the chain of troops to cover the quarters well: which is done either behind a river, under cover of a range of strong posts, or under the protection of fortified towns. Hussars are very useful on this service.

It should be observed, as an invariable maxim, in winter-quarters, that your regiments be disposed in brigades, to be always under the eye of a general officer; and, if possible, let the regiments be so distributed, as to be each under the command of its own chief.

QUARTERING, in heraldry, is dividing a coat into four or more quarters, or quarterings, by parting, coupling, &c. that is, by perpendicular and horizontal lines, &c.

QUARTO-DECIMANS, an ancient sect in the Christian church, who taught that Easter should always be celebrated according to the custom of the Jews, on the fourteenth day of the moon in the month of March, whensoever that day fell out. And hence they derived their name *quarto decimani*, q. d. Fourteenthers. The Asiatics were mightily attached to this opinion, pre-

tending that it was built on the authority of St John, who was their apostle; and pope Victor could never bring them to obedience in this article, though he was upon the point of excommunicating them: but it is more probable he contented himself with menaces. See **EASTER**.

QUARTZ, a genus of siliceous earths very common in Europe. According to Kirwan, the quartz are in general the purest of the siliceous kind, though most of them contain a slight mixture of other earths: the most obvious distinction among them arises from their opacity or transparency. Cronstedt gives the following characteristics of it: 1. It is generally cracked throughout, even in the rock itself, whereby, as well as by its own nature, it breaks into irregular and sharp fragments. 2. It cannot be easily made red hot, without cracking still more. 3. It never decays in the air. 4. Melted with fixed alkali in a due proportion, it gives a more solid and fixed glass than any of the other siliceous stones. 5. When there has been no interruption in its natural accretion, it always crystallizes into hexagonal prisms pointed at both ends. 6. It is met with in clefts, fissures, and small veins in rocks; it seldom forms large veins, and still more rarely whole mountains, without a mixture of heterogeneous substances. It is found,

1. Pure, of several varieties, as, (1.) Solid, or having no visible particles, and called *fat quartz*. This is either transparent, white, blue, or violet-coloured. The first kind is met with in the copper-mines in the northern part of Norway and Siberia, and has no regular form, but is as clear as the finest crystallized quartz, or rock crystal. (2.) *Grained quartz*, of a white or pale green colour, found in various places in Sweden. (3.) *The sparry quartz*, which is the scarcest of the whole, and ought not to be confounded with the white felt-spar, because it is of a smoother appearance, and breaks into larger and more irregular planes. It is found of a whitish yellow, from the gold mines in Hungary; or white, from the island of Uto. Brunnich tells us, that the Hungarian gold and silver mines near Hoderich, which have veins frequently some fathoms wide, afford a kind of lamellated and porous quartz. It is met with of white, yellow, and blue colours, and it is sometimes finely crystallized in pyramidal figures.

2. *Crystallized quartz*, or *rock crystal*. See **CRYSTAL**.

3. *Impure quartz*. Of this there are two kinds, (1.) Mixed with iron, in form of a black calx. It is black, glossy, and contains a great quantity of iron. It is found in Sweden. (2.) Mixed with copper, and of a red colour, found in the same country.

Cronstedt observes, that quartz in general, and especially its crystals, are very commonly supposed, when yet in their soft and dissolved state, to have included within them some vegetables, for instance grass and moss. "This (says he) I cannot absolutely deny; but it deserves carefully to be examined if that which is shown as a grass be not an asbestos, or a striated cockle; and the moss only branched varieties filled with earth, which, by their being ramose, bear a vegetable appearance. It is very common in agates, and makes them of less value than they otherwise would be. This is most generally the case with those stones which are shown as including vegetables; and, for my own part, I have

Quartz
||
Quasi.

have never been so fortunate as to meet with any others."

M. Magellan remarks, that quartz is one of the principal kinds of stone which contain metals. Some of the Hungarian veins consist entirely of it, and the gold is so minutely dispersed, that it cannot be discerned by the best microscopes before it is separated by pounding and washing. The width of the veins, some of which are half a fathom, and some still more, repay the trouble and expences, which the small quantity of gold would not otherwise counterbalance. Nature has not any where produced mountains of pure quartz; for though some rocks in Sweden are ranked among the quartzes, they are undoubtedly mixed with heterogeneous matters. Near Lauterberg upon the Hartz are veins of this stone from one to three fathoms wide, consisting of a loose sand, in which they find the copper ore in nests. In the Danish isle of Anhalt we meet with triangular quartz pebbles. There are likewise crystals of quartz having water inclosed in them; some fine pieces of this kind are to be met with in the Imperial cabinet at Vienna, &c.

Rock crystals are generally found upon or among quartz, and are to be met with in all parts of the world. The greatest number are furnished to the European countries from Mount Saint Gothard in Switzerland.—Here large pieces, weighing from 5 to 800 pounds, were found at Grimselberg; one of 1200 pounds was found some years ago at Fribach in the Wallais; and a piece six feet long, four broad, and equally thick, was found in the island of Madagascar, a place where these natural productions are of the most extraordinary size and perfection.

When great quantities of quartz are continually agitated by the sea or river water, they are sometimes reduced to such very minute parts as to be easily carried away, suspended in the water; and there are sands of so minute a size as to measure less than the two or three hundredth part of an inch. These are called *quick-sands*. Immense tracts of land consist only of loose sands, particularly along the sea-shore in many parts of Europe. Some suppose that sea-water has the power of producing this sand out of its own substance; and their surfaces, in general, are so polished, as to show that they could not be reduced in size by rubbing against each other; but we know not as yet that such a production has ever been demonstrated. When sand is about as big as peas, it is called gravel; and when it is free from saline and heterogeneous particles, it is employed in making mortar, and other economical purposes. That which is very pure serves for making flint-glass, with red calces of lead, and the proper alkaline flux; but when mixed with ferruginous black sand, the glass assumes a greenish black colour. "This (says M. Magellan) I have seen among the various specimens of glass made by Mr E. Delaval, F. R. S. who produced a very fine transparent and colourless glass out of the same sand with which he had made some of that black glass, and this only by separating from it all the ferruginous mixture."

QUASHING, in law, the overthrowing and annulling a thing.

QUASI-CONTRACT, in the civil law, an act without the strict form of a contract, but yet having the force thereof. In a contract there must be the mutual consent of both parties, but in a *quasi-contract* one party

may be bound or obligated to the other, without having given his consent to the act whereby he is obliged. For example: I have done your business, in your absence, without your procuration, and it has succeeded to your advantage. I have then an action against you for the recovery of what I have disbursed, and you an action against me to make me give an account of my administration, which amounts to a *quasi-contract*.

QUASI-CRIME, or *Quasi-deliâ*, in the civil law, the action of a person who does damage, or evil, involuntarily. The reparation of *quasi-crimes* consists in making good the damages, with interest.

QUASS, a fermented liquor drunk in Russia. See PEASANT.

QUASSIA, in botany: A genus of the monogynia order, belonging to the decandria class of plants; and in the natural method ranking under the 14th order, *Gruinales*. The calyx is pentaphyllous; there are five petals; the nectarium is pentaphyllous; there are from two to five seed-cases standing asunder, and monospermous. There are three species, the *amara*, *simaruba*, and *excelsa* or *polygama*.

The quassia *amara* grows to the height of several feet, and sends off many strong branches. The wood is of a white colour and light; the bark is thin and grey: the leaves are placed alternately on the branches, and consist of two pair of opposite pinnæ, with an odd one at the end: all the leaflets are of an elliptical shape, entire, veined smooth, pointed, sessile, on the upper pagina of a deep green colour, on the under paler: the common footstalk is articulated, and winged, or edged, on each side with a leafy membrane, which gradually expands towards the base of the pinnæ: the flowers are all hermaphrodite, of a bright red colour, and terminate the branches in long spikes: the bractæ or floral leaves are lance-shaped or linear, coloured, and placed alternately upon the peduncles: the calyx is small, persistent, and five-toothed: the corolla consists of five lance-shaped equal petals, at the base of which is placed the nectary, or five roundish, coloured, scales: the filaments are ten, slender, somewhat longer than the corolla, and crowned with simple antheræ, placed transversely: the receptacle is fleshy and orbicular: the germen is ovate, divided into five parts, and supports a slender style, longer than the filaments, and terminated by a tapering stigma: the capsules are five, two-celled, and contain globular seeds. It is a native of South America, particularly of Surinam, and also of some of the West Indian islands. The root, bark, and wood, of this tree have all places in the *materia medica*. The wood is most generally used, and is said to be a tonic, stomachic, antiseptic, and febrifuge.

The quassia *simaruba* is common in all the woodlands in Jamaica. It grows to a great height and considerable thickness. The trunks of the old trees are black and a little furrowed. Those of the young trees are smooth and gray, with here and there a broad yellow spot. The inside bark of the trunk and branches is white, fibrous, and tough. It tastes slightly bitter. On cutting or stripping off this bark, no milky juice issues, as has been mentioned by various authors. The wood is hard, and useful for buildings. It splits freely, and makes excellent staves for sugar hogsheds. It has no sensible bitter taste. The branches are alternate and spreading. The leaves are numerous and alternate. On the upper side, they are smooth, shining, and of a deep

Wood-ville's Medical Botany, Vol. ii. p. 215.

Dr Wright's Paper, Edin. 1 ranf. vol. ii.

Quassia. deep green colour: on the under side they are white. The flowers appear about the beginning of April. They are of a yellow colour, and placed on spikes beautifully branched.

The fruit is of that kind called a *drupa*, and is ripe towards the end of May. It is of an oval shape, is black, smooth, and shining. The pulp is fleshy and soft; the taste a nauseous sweet. The nut is flattened, and on one side winged. The kernel is small, flat; and tastes sweet. The natural number of these drupæ is five on each common receptacle; but, for the most part, there are only two or three; the rest abort by various accidents. The roots are thick, and run superficially under the surface of the ground to a considerable distance. The bark is rough, scaly, and warted. The inside when fresh is a full yellow, but when dry paler. It has but little smell. The taste is bitter, but not very disagreeable. This is the true cortex *simarubæ* of the shops. This tree is known in Jamaica by the names of *mountain damson*, *bitter damson* and *stave-wood*. The shops are supplied with this bark from Guiana; but now we may have it from our own islands at a moderate expence. On examining the fructification, Dr Wright found this tree to be a species of *quassia*. Under that name he sent it to Europe, and Linnæus adopted it into his system. There are male flowers on one tree and female flowers on another; and this is invariably the case in Jamaica.

Most authors who have written on the *simaruba* agree, that in fluxes it restores the lost tone of the intestines, allays their spasmodic motions, promotes the secretions by urine and perspiration, removes that lowness of spirits attending dysenteries, and disposes the patient to sleep; the gripes and tenesmus are taken off, and the stools are changed to their natural colour and consistence. In a moderate dose, it occasions no disturbance or uneasiness; but in a large doze it produces sickness at stomach and vomiting. Negroes are less affected by it than white people. Dr Cullen, however, says, "We can perceive nothing in this bark but that of a simple bitter; the virtues ascribed to it in dysentery have not been confirmed by my experience, or that of the practitioners in this country; and, leaving what others are said to have experienced to be further examined and considered by practitioners, I can only at present say, that my account of the effect of bitters will perhaps explain the virtues ascribed to *simaruba*. In dysentery I have found an infusion of chamomile flowers a more useful remedy." The *quassia excelsa* or *polygama* was named by Sir Joseph Banks, Dr Solander, and Dr Wright, *pricrania amara* (see *PRICRANIA Amara*.) It is ranked, however, by Mr John Lindsay, in a paper in the third volume of the Edinburgh Transactions, under *quassia*, who gives the following description of it. "It is very common in the woodlands of Jamaica, is beautiful, tall, and stately, some of them being 100 feet long and ten feet in circumference eight feet above the ground. The trunk is straight, smooth, and tapering, sending off its branches towards the top. The outside bark is pretty smooth, of a light grey or ash colour, from various lichens. The bark of the roots is of a yellow cast, somewhat like the cortex *simarubæ*. The inner bark is tough, and composed of fine flaxy fibres. The wood is of a yellow colour, tough, but not very hard. It takes a good polish, and is used

VOL. XV.

as flooring. The leaves are sub-alternate; the small leaves are in pairs, from five to eight, standing opposite to each other on short footstalks, and ending with an odd one. They are of an oblong oval shape, and pointed; the ribs reddish, and the young leaves are covered with a fine brownish down. The flowers come out in bunches or clusters from the lower part of the last shoot before the leaves, and stand on round footstalks. The flowers are small, of a yellowish green colour, with a very small calyx. The male or barren tree has flowers nearly similar to the hermaphrodite, but in it there are only the rudiments of a style.

"The fruit is a smooth black drupa, round-shaped, and of the size of a pea. There is but little pulp, and the nut covers a round kernel. These drupæ are generally three, sometimes two, and often only one, attached sidewise to a roundish fleshy receptacle. It flowers in October and November, and its fruit is ripe in December and January. Except the pulp of the fruit, every other part of this tree has an intensely bitter taste. In taste and virtues it is nearly equal to the *quassia* of Surinam and I am credibly informed is sold in London for the *quassia amara*; and it may be safely used in all cases where that drug has been thought proper, whether as an antiseptic, or in cases of weakness in the stomach and bowels. It may either be given alone, or joined with the Jesuit's bark. The happiest effects result from the use of this medicine in obstinate remitting fevers from marsh miasmata, in agues which had resisted the use of Jesuit's bark and in dysenteries of long standing. It is in daily practice in dropries from debility, either in simple infusions or tincture by itself, or joined with aromatics and chalybeates. Dr Drummond, an eminent physician in Jamaica, prescribes it with great success in the above cases as well as in amenorrhæa, chlorosis, dyspepsia, and in that species of pica called *dirteating*, so fatal to a number of negroes.

"The bark of the *quassia polygama*, but especially the wood, is intensely bitter. They may both be used in various forms. In certain cases of dropsy, aromatics and preparations are joined to it also in amenorrhæa and chlorosis; and in worm fevers, the cabbage-bark, or other vegetable anthelmintics."

QUATUORVIR, in antiquity, formerly written IIII. VIR, a Roman magistrate, who has three colleagues joined with him in the same administration, and had the care of conducting and settling the colonies sent into the provinces. There were also *quatuorviri* appointed to inspect and take care of repairs, &c.

QUAVER, in music, a measure of time equal to half a crotchet, or an eighth part of a semibreve.

QUAY. See KEY.

QUEBEC, a handsome and large town of America, and capital of Canada. The first place taken notice of upon landing here is a square of an irregular figure, with well-built houses on each side; on the back of which is a rock; on the left it is bounded by a small church; and on the right are two rows of houses, parallel to each other. There is another between the church and the harbour; as also another long row on the side of the bay. This may be looked upon as a kind of suburb; and between this and the great street is a very steep ascent, in which they have made steps for the foot-passengers to go up. This may be called the

Quebec
Queen.

the *Upper Town*, wherein is the bishop's palace; and between two large squares is a fort where the governor lodges. The Recolets have handsome houses over-against it, and on the right is the cathedral church: over-against this is the Jesuits college, and between them are well-built houses; from the fort runs two streets, which are crossed by a third, and between these is a church and a convent. In the second square are two descents to the river of St Charles. The Hotel Dieu is in the midway; and from thence are small houses, which reach to the house of the intendant. On the other side of the Jesuits college, where the church stands, is a pretty long street in which is a nunnery. Almost all the houses are built of stone, and there are about 7000 inhabitants; the fort is a handsome building, but not quite finished. Quebec is not regularly fortified: but it cannot be easily taken; for the harbour is flanked with two bastions, which at high tides are almost level with the water. A little above one of the bastions is a demi-bastion, partly taken out of the rock; and above it, on the side of the gallery of the fort is a battery, of 25 pieces of cannon: still above this is a square fort called the *citadel*; and the ways from one fortification to another are difficult to pass. To the left of the harbour, on the side of the road, there are large batteries of cannon, and some mortars; besides these, there are several other fortifications not very easy to be described. In 1711 the British fitted out a fleet with a design to conquer Canada, which failed on account of the rashness of the admiral; who, contrary to the advice of his pilot, went too near the Seven isles, and so lost his largest ships, and 3000 of his best soldiers. It is about 300 miles north-west of Boston in New-England. On October 18. 1759, it was taken by the British under the command of General Wolfe, who lost his life in the battle, after he had the satisfaction to know that his troops were victorious. Admiral Saunders commanded a squadron of men of war, and did immense service in reducing this place; there being not a man in the navy but what was active on this occasion, not excepting the sailors belonging to the transport vessels. After this valuable acquisition, all Canada came under the jurisdiction of the crown of Great Britain. W. Long. 69. 48. N. Lat. 46. 55.

QUEDA, a kingdom of Asia, in the peninsula beyond the Ganges, and near the strait of Malacca. The king is tributary to Siam. The principal town is of the same name, and said to contain about 8000 inhabitants; and is subject to the Dutch. It has a harbour, and is 300 miles north of Malacca. E. Long. 100. 5. N. Lat. 7. 5.

QUEDLINGBURG, a town of Germany, in the circle of Upper Saxony, and on the confines of the duchy of Brunswick. Here is a famous abbey, whose abbeys is a princess of the empire, and who sends deputies to the diets. Her contingent is one horseman and ten footmen. The inhabitants of the town live by brewing, husbandry, and feeding of cattle. It is 10 miles south-east of Halberstadt, and 32 west of Bernberg. E. Long. 11. 34. N. Lat. 52. 1.

QUEEN, a woman who holds a crown singly.

The title of *queen* is also given by way of courtesy to her that is married to a king, who is called by way of distinction *queen-consort*; the former being termed *queen-regent*. The widow of a king is also called *queen*,

but with the addition of *dowager*. See *Royal-Family*.

QUEEN Charlotte's Sound, is situated at the northern extremity of the southern island of New Zealand, near Cook's Strait, lying in 41. 6. of south latitude, and 174. 19. of east longitude. The climate of this sound is much more mild than at Dusky Bay; and though there is not such plenty of wild fowl and fish, the defect is sufficiently compensated by abundance of excellent vegetables. The hills about the sound consist mostly of an argillaceous stone of a greenish grey, or bluish or yellowish brown colour. A green talkous or nephritic (by the jewellers called *jadde*) is likewise very common, together with horn-stone, shingle, several sorts of flinty stones and pebbles, some loose pieces of basaltes, strata of a compact mica or glimmer, with particles of quartz. Hence, Mr Forrester thinks, there is reason to believe that this part of New Zealand contains iron-ore, and perhaps several other metallic substances. The country is not so steep as at Dusky Bay, and the hills near the sea are generally inferior in height, but covered with forests equally intricate and impenetrable. Captain Cook sowed the seeds of many vegetables in this place, that have useful and nutritive roots. He sowed also corn of several sorts, beans, kidney-beans, and pease. The dogs here are of the long-haired sort, with pricked ears, and resemble the common shepherd's cur, but they are very stupid animals. They are fed with fish, and even dogs flesh, and perhaps human flesh, which the natives also eat. Captains Cook and Furneaux left on these islands a boar and two sows, with a pair of goats, male and female, with some geese, in order to benefit the natives and future generations of navigators. They left likewise among them a number of brass medals gilt, on one side of which was the head of his present majesty, with the inscription George III. King of Great Britain, France, and Ireland, &c. On the reverse, a representation of two men of war, with the names Resolution and Adventure over them; and the exergue, sailed from England March MDCCCLXXII.

QUEEN-Gold, is a royal duty or revenue belonging to every queen of England during her marriage to the king, payable by persons in the kingdom and Ireland, on divers grants of the king by way of fine or oblation, &c. being one full tenth part above the entire fines, on pardons, contracts, or agreements, which becomes a real debt to the queen, by the name of *aurum regina* upon the party's bare agreement with the king for his fine, and recording the same.

QUEEN'S-County, a division of the province of Leinster in Ireland; so called from the popish Queen Mary, in whose reign it was first made a county by the earl of Sussex, then lord-deputy. It is bounded on the south by Kilkenny and Catherlogh; by King's county on the north and west; part of Kildare and Catherlogh on the east; and part of Tipperary on the west. Its greatest length from north to south is 35 miles, and its breadth near as much; but it is unequal both ways. This county was anciently full of bogs and woods, though now pretty well inclosed, cultivated, and inhabited. The baronies contained in it are seven; and it sends eight members to parliament.

QUEEN-Bee. See *BEE*, n^o 3. &c.

QUEENBOROUGH, a town of the isle of Sheppey

Queen
Queenborough.
rough.

Queens-
ferry
||
Quercus.

pey in Kent, which sends two members to parliament, though consisting only of about 100 low brick houses, and scarce 350 inhabitants. The chief employment of the people here is oyster drudging; oysters being very plentiful, and of a fine flavour. E. Long. o. 50. N. Lat. 51. 25.

QUEENS-FERRY, a town of Scotland, in the shire of Lothian, seated on the south side of the river Forth, 9 miles west of Edinburgh.

Grolier's
General
Description
of China.

QUEI-LING-FOU, the capital of the province of Quangsi in China, has its name from a flower called *qui*, which grows on a tree resembling a laurel; it exhales so sweet and agreeable an odour, that the whole country around is perfumed with it. It is situated on the banks of a river, which throws itself into the Taho; but it flows with such rapidity, and amidst so narrow valleys, that it is neither navigable nor of any utility to commerce. This city is large, and the whole of it is built almost after the model of our ancient fortresses; but it is much inferior to the greater part of the capitals of the other provinces. A great number of birds are found in the territories belonging to it, the colours of which are so bright and variegated, that the artists of this country, in order to add to the lustre of their silks, interweave with them some of their feathers, which have a splendor and beauty that cannot be imitated. Quei-ling has under its jurisdiction two cities of the second class and seven of the third.

QUEI, in natural history, is a name given by the Chinese to a peculiar earth found in many parts of the east. It is of the nature of an indurated clay, and in some degree approaches to the talcs, as our steatites and the galactites do. It is very white and absterfivc, used by the women of China to take off spots from the skin, and render it soft and smooth, as the Italian ladies use talc of Venice. They sometimes use the fine powder of this stone dry, rubbing it on the hands and face after washing; sometimes they mix it in pomatum.

QUERCI, a province of Guienne in France; bounded on the north by Limosin, on the east by Rouergue and Auvergne, on the south by Upper Languedoc, and on the west by Agenois and Perigord. It is divided into Upper and Lower; and is fertile in corn, wine, and fruits. Cahors in the capital town.

QUERCUS, the OAK-TREE: A genus of the polyandria order, belonging to the monoecia class of plants; and in the natural method ranking under the 50th order, *Amentaceæ*. The calyx is nearly quinquefid; there is no corolla; the stamina are from five to ten in number. The female calyx is monophyllous, very entire, and scabrous. There is no corolla; the styles are from two to five; and there is an ovate seed. See OAK.

Species. 1. The robur, or common English oak, grows from about 60 or 70 to 100 feet high, with a prodigious large trunk, and monstrous spreading head; oblong leaves, broadest towards the top, the edges acutely sinuated, having the angles obtuse. There is a variety, having the leaves finely striped with white. This species grows in great abundance all over England, in woods, forests, and hedge-rows; is naturally of an amazing large growth; there being accounts of some above 100 feet stature, with wonderful large trunks and spreading heads; and is supposed to continue its growth many centuries.

Quercus.

2. The prinus, or chestnut-leaved American oak, grows 50 or 60 feet high; having large oblong-oval smooth leaves pointed both ways, the edges sinuated-ferrated, with the sinuses uniformly round.

3. The phellos, or willow-leaved American oak, grows 40 or 50 feet high, having long narrow smooth entire leaves, like those of the willow. There is a variety called the *dwarf willow-leaved oak*.

4. The alba, or white Virginian oak, grows 30 or 40 feet high, having a whitish bark, with long obliquely-pinnatifid light-green leaves, the sinuses and angles obtuse.

5. The nigra, or black Virginian oak, grows 30 or 40 feet high, having a dark-coloured bark, large wedge-shaped slightly-trilobated leaves.

6. The rubra, or red Virginian oak, grows about 60 feet high, having a dark-greyish bark, long obtusely-sinuated leaves, with the sinuses terminated by bristly points, and have sometimes red spotted veins, but generally dyeing in autumn to a reddish colour, remaining on the trees late in the season.

7. The esculus of Pliny, or cut-leaved Italian oak, grows about 30 feet high, having a purplish bark, oblong deeply-sinuated smooth leaves, and long slender close-fitting acorns in very large cups.

8. *Ægilops*, or large prickly-cupped Spanish oak, grows 70 or 80 feet high or more, with a very large trunk, and widely-spreading head, having a whitish bark, large oblong-oval deeply-ferrated smooth leaves, the ferratures bowed backward, and large acorns placed in singularly large prickly cups. This is a noble species, almost equal in growth to the common English oak.

9. Cerris, or smaller prickly-cupped Spanish oak, grows 30 or 40 feet high, and has oblong lyre-shaped pinnatifid transversely-jagged leaves, downy underneath, and small acorns placed in prickly cups.

10. The ilex, or common evergreen oak, grows 40 or 50 feet high, having a smooth bark, oval and oblong undivided ferrated petiolated leaves, downy and whitish underneath. The varieties are, broad-leaved, narrow-leaved, and sometimes both sorts and other different shaped leaves on the same tree, also sometimes with sawed and prickly leaves.

11. The gramuntia or Montpellier holly-leaved evergreen oak, grows 40 or 50 feet high; and has oblong-oval, close-fitting sinuated spinous leaves, downy underneath, bearing a resemblance to the leaves of holly.

12. The fuber, or cork-tree, grows 30 or 40 feet high, having a thick, rough, fungous, cleft bark, and oblong-oval undivided ferrated leaves, downy underneath. This species furnishes that useful material cork; it being the bark of the tree, which becoming of a thick fungous nature, under which, at the same time, is formed a new bark, and the old being detached for use, the tree still lives, and the succeeding young bark becomes also of the same thick spongy nature in six or seven years, fit for barking, having likewise another fresh bark forming under it, becoming cork like the others in the like period of time; and in this manner these trees wonderfully furnish the cork for our use, and of which is made the corks for bottles, bungs for barrels, and numerous other useful articles. The tree grows in great plenty in Spain and Portugal, and from these countries we receive the cork. The Spaniards

Quercus. burn it, to make that kind of light black we call Spanish black, used by painters. Cups made of cork are said to be good for hysterical persons to drink out of. The Egyptians made coffins of cork; which being lined with a resinous composition, preserved dead bodies uncorrupted. The Spaniards line stone-walls with it, which not only renders them very warm, but corrects the moisture of the air.

13. The coccifera, scarlet, or kermes oak, grows but 14 or 15 feet high, branching all the way, and of bushy growth; with large oval, undivided, indented, spinous leaves; and producing small glandular excrescences, called *kermes* or *scarlet grain*, used by the dyers. The small scarlet glands found in this tree, is the effect of certain insects depositing their eggs betwixt the bark of the branches and leaves, causing an extravasation of the sap, and forming the excrescence or substance in question, which being dried is the kermes or scarlet pastel.

14. The Molucca, Moluccan oak, commonly called *American live oak*, grows about 40 feet high, having oval, spear-shaped, smooth, entire leaves, and small oblong eatable acorns.

All the above 14 species of *quercus* produce flowers annually in the spring, about April or May, of a yellowish colour, but make no ornamental appearance, and are males and females separated in the same tree; the males being in loose amentums, and the females sitting close to the buds in thick leathery hemispherical calyxes, succeeded by the fruit or acorns, which are oval nuts fixed by their base into rough permanent cups, and mostly sit quite close, and some on short footstalks, ripening in autumn; which in the common English oak is in great abundance, and often in tolerable plenty on some of the other sorts: those of all the kinds serve for propagating their respective species; they are also excellent food for swine and deer, the common oak in particular.

Uses, &c. Oak-trees, of all the above sorts may be employed in gardening to diversify large ornamental plantations in out-grounds, and in forming clumps in spacious lawns, parks, and other extensive opens; the evergreen kinds in particular have great merit for all ornamental purposes in gardens. But all the larger growing kinds, both deciduous, and evergreens, demand esteem principally as first-rate forest-trees for their timber. The English oak, however, claims precedence as a timber-tree, for its prodigious height and bulk, and superior worth of its wood. Every possessor of considerable estates ought therefore to be particularly assiduous in raising woods of them, which is effected by sowing the acorns either in a nursery and the plants transplanted where they are to remain, or sowed at once in the places where they are always to stand. All the sorts will prosper in any middling soil and open situation, though in a loamy soil they are generally more prosperous: however, there are but few soils in which oaks will not grow; they will even thrive tolerably in gravelly, sandy, and clayey land, as may be observed in many parts of this country of the common oak.

The oak is of the utmost importance to Britain, and its cultivation deserves the utmost attention. Much, therefore, to the honour of the members of the *London Society for encouraging Arts, Manufactures, and Commerce*, they have excited particular attention to it; and many

excellent observations, drawn from practice, will be found in their Transactions. *Quercus.*

The propagation of the striped-leaved varieties of the common oak, and any particular variety of the other species, must be effected by grafting, as they will not continue the same from seed: the grafting may be performed upon any kind of oakling-stocks raised from the acorns, and train them for standards like the others.

The oak is remarkable for its slowness of growth, bulk, and longevity. It has been remarked that the trunk has attained to the size only of 14 inches in diameter, and of some to 20, in the space of fourscore years. As to bulk, we have an account of an oak belonging to Lord Powis, growing in Broomfield wood, near Ludlow in Shropshire, in the year 1764, the trunk of which measured 68 feet in girth, 24 in length, and which, reckoning 90 feet for the large branches, contained in the whole 1455 feet of timber, round measure, or 29 loads and five feet, at 50 feet to a load.

The Greendale oak, &c. we have already mentioned (see OAK). In the opinion of many, the Cowthorpe oak near Wetherby in Yorkshire is the father of the forest. Dr Hunter, in his edition of Evelyn, has given an engraving of it. Within three feet of the surface he says it measures 16 yards, and close to the ground 62. In 1776, though in a ruinous condition, it was 85 feet high, and its principal limb extended 16 yards from the bole. The foliage was very thin. If this measurement were taken as the dimension of the *real stem*, the size of this tree would be enormous; but like most very large trees, its stem is short, spreading wide at the base, roots rising above the ground like buttresses to the trunk, which is similar not to a cylinder but to the frustum of a cone. Mr Marshall says, "I found it in 1768, at four feet, 40 feet 6 inches; at five feet, 36 feet 6 inches; and at six feet, 32 feet 1 inch." In the principal dimensions then, *the size of the stem*, it is exceeded by the Bentley oak; of which the same writer gives the following account: "In 1759 the oak in Holt-Forest, near Bentley, was at 7 feet 34 feet. There is a large excrescence at 5 and 6 feet that would render the measure unfair. In 1778, this tree was increased half an inch in 19 years. It does not appear to be hollow, but by the trifling increase I conclude it not sound." These dimensions however, are exceeded by those of the Boddington oak. It grows in a piece of rich grass land, called the *Old Orchard Ground*, belonging to Boddington Manor-Farm, lying near the turnpike-road between Cheltenham and Tewksbury, in the Vale of Gloucester. The stem is remarkably collected at the root, the sides of its trunk being much more upright than those of large trees in general; and yet its circumference at the ground is about 20 paces; measuring with a two-foot rule, it is more than 11 yards. At three feet high it is 42 feet, and where smallest, *i. e.* from five to six feet high, it is 36 feet. At six feet it swells out large, and forms an enormous head, which has been furnished with huge, and probably extensive, arms. But time and the fury of the wind have robbed it of much of its grandeur; and the greatest extent of arm in 1783 was eight yards from the stem.

In the Gentleman's Magazine for May 1794 we have an account of an oak tree growing in Penshurst park

Quercus. park in Kent together with an engraving. It is called the *Bear* or *Bear oak*, from being supposed to resemble that which Camden thought gave name to the county of Berkshire. The tradition at Penshurst is that it is the very tree planted on the day that the celebrated Sir Philip Sydney was born. "Some late writers (says Mr Rawlet) have questioned this, and think that to have been a different tree, which was cut down some years ago, and was indeed much larger than this. I remember being once in the hollow of the present oak with the late Sir John Cullum; and his opinion then was, that its antiquity was greater than the period assigned. But, I assure you, the tradition of this place is constant for this tree; and, in confirmation of it, an old lady of 94 years of age, now living, has told me, that all the tenants used to furnish themselves with boughs from this tree, to stick in their hats, whenever they went to meet the earls of Leicester, as was always the custom to do at the end of the park when they came to reside at their seat here. This fine old oak stands upon a plain about 500 yards from their venerable mansion, near a large piece of water called *Lancup-well*. Ben Jonson and Waller have particularly noticed it; and, from the distinguished owners of this place, it may be truly said to stand on classic ground. Within the hollow of it there is a seat, and it is capable of containing five or six persons with ease. The bark round the entrance was so much grown up, that it has lately been cut away to facilitate the access. The dimensions of the tree are these:

	Feet.	Inches.
Girth close to the ground	35	6
Ditto one foot from ditto	27	6
Ditto five feet from ditto	24	0
Height taken by shadow	73	0
Girth of lowest, but not largest, limb	6	9

With respect to longevity, Linnæus gives account of an oak 260 years old: but we have had traditions of some in England (how far to be depended upon we know not) that have attained to more than double that age. Mr Marham, in a letter to Thomas Beever, Esq; Bath Papers, Vol. I. p. 79, makes some very ingenious calculations on the age of trees, and concludes from the increase of the Bentley oak, &c. that the Fortworth chestnut is 1100 years old.

Besides the grand purposes to which the timber is applied in navigation and architecture, and the bark in tanning of leather, there are other uses of less consequence, to which the different parts of this tree have been referred. The Highlanders use the bark to dye their yarn of a brown colour, or, mixed with copperas, of a black colour. They call the oak *the king of all the trees in the forest*; and the herdsman would think himself and his flock unfortunate if he had not a staff of it. The acorns are a good food to fatten swine and turkeys; and, after the severe winter of the year 1709, the poor people in France were miserably constrained to eat them themselves. There are, however, acorns produced from another species of oak, which are eaten to this day in Spain and Greece, with as much pleasure as chestnuts, without the dreadful compulsion of hunger.

Quercus Marina, the *Sea Oak*, in botany, the name of one of the broad-leaved dichotomous sea-fucuses. It is not agreed, among the late botanists, what was the

sea oak of Theophrastus; and the most ancient botanists, Clusius and Cæsalpinus, suppose it to have been a species of the shrubby coralline; but that seems by no means to have been the case, since Theophrastus says his sea oak had a long, thick, and fleshy leaf; whence we may much more naturally conclude it to have been of the fucus class.

QUERIA, in botany: A genus of the trigynia order, belonging to the triandria class of plants; and in the natural method ranking under the 22d order, *Caryophylli*. The calyx is pentaphyllous; there is no corolla; the capsule is unilocular, and trivalved, with one seed. There are two species, *viz.* hispanica and canadensis.

QUESNE (Abraham du), marquis of Quesne, admiral of the naval forces of France, and one of the greatest men of the last age, was born in Normandy in 1610. He contributed to the defeating of the naval power of Spain before Gattari; was dangerously wounded before Barcelona in 1642, and on other occasions; he went into the service of the Swedes, and became vice-admiral; gave the Danes an entire defeat, killed their admiral, and took his ship. He was recalled into France in 1647, and commanded the squadron sent to Naples. The sea-affairs of France being much fallen, he fitted out divers ships for the relief of the royal army that blocked up Bourdeaux; which was the principal cause of the surrender of the town. He was very fortunate in the last wars of Sicily, where he beat the Dutch thrice, and De Ruyter was killed. He also obliged the Algerines to sue for peace from France in a very humble manner. In short, Asia, Africa, and Europe, felt the effects of his valour. He was a Protestant; yet the king bestowed on him the land of Bouchet, and to immortalize his memory gave it the name of that great man. He died in 1688.

QUESTION, in logic, a proposition stated by way of interrogation.

QUESTION, or *Torture*. See **RACK**.

QUESTOR, or *Quæstor*, in Roman antiquity, an officer who had the management of the public treasure.

The questorship was the first office any person could bear in the commonwealth, and gave a right to sit in the senate.

At first there were only two; but afterwards two others were created, to take care of the payment of the armies abroad, of selling the plunder, booty, &c. for which purpose they generally accompanied the consuls in their expeditions; on which account they were called *peregrini*, as the first and principal two were called *urbani*.

The number of the questors was afterwards greatly increased. They had the keeping of the decrees of the senate: and hence came the two officers of *questor principis*, or *augusti*, sometimes called *candidatus principis*, whose office resembled in most respects that of our secretaries of state; and the *questor palatii*, answering in a great measure to the English lord-chancellor.

QUEUE, in heraldry, signifies the tail of a beast: thus, if a lion be born with a forked tail, he is blazoned double-queued.

QUEVEDO de **VILLEGAS** (Francisco), a celebrated Spanish poet, born at Madrid in 1570. He was descended from a noble family, and was made a knight of

Queria
Quevedo.

Quick, Quicklime. of St James; but was thrown into prison by order of Count Olivarez, whose administration he satirized in his verses, and was not set at liberty till after that minister's disgrace. Quevedo wrote some heroic, lyric, and facetious poems. He also composed several treatises on religious subjects, and has translated some authors into Spanish. He died in 1645. The most known of his works are, 1. The Spanish Parnassus. 2. The Adventurer Bufcon. 3. Visions of Hell Reformed, &c. Quevedo was one of the greatest scholars and most eminent poets of his time. His youth was spent in the service of his country in Italy, where he distinguished himself with the utmost sagacity and prudence. His moral discourses prove his sound doctrine and religious sentiments, while his literary pieces display his infinite judgment and refined taste. His great knowledge of Hebrew is apparent from the report of the historian Mariana to the king, requesting that Quevedo might revise the new edition of the Bible of Arias Montanus. His translations of Epictetus and Phocylides, with his imitations of Anacreon, and other Greek authors, show how well he was versed in that language: that he was a Latin scholar, his constant correspondence, from the age of twenty, with Lipsius, Chifflet, and Scioppius, will sufficiently illustrate. As a poet, he excelled both in the serious and burlesque style, and was singularly happy in that particular turn we have since admired in Butler and Swift. His library, which consisted of about five thousand volumes, was reduced at his death to about two thousand, and is preserved in the convent of St Martin at Madrid.

QUICK, or *QUICKSET Hedge*, among gardeners, denote all live hedges, of whatever sort of plants they are composed, to distinguish them from dead hedges; but in a more strict sense of the word, it is restrained to those planted with the hawthorn, under which name those young plants or sets are sold by the nursery-gardeners who raise them for sale. See the article **HEDGES**.

QUICKLIME, a general name for all calcareous substances when deprived of their fixed air; such as chalk, limestone, oyster-shells, &c. calcined. See **CHEMISTRY**, n° 511, 748, 837, and 914.

Quicklime has the following properties. 1. It is entirely soluble in water, with which it unites so rapidly as to occasion considerable heat. When exposed to air, it imbibes moisture from thence. When united with as much water as is sufficient to make it a fluid paste, it is called *slaked lime*. Water saturated with quicklime is called *lime-water*. According to Brandt, lime-water contains about one part of quicklime to 700 or 800 parts of water. Slaked lime, or lime-water, being exposed to the atmosphere, attract from thence particles of fixable air which float in it, by which means the quicklime is rendered mild, insoluble in water, and therefore appears on the surface of the lime-water, or of the slaked lime where this combination happens, in the state of mild or combined calcareous earth, convertible by a second calcination into quicklime, and is called *cream of lime*.

If the earth dissolved in lime-water be precipitated from thence by any substance containing fixable air, as by mild alkalis or magnesia, it will unite with this air, become mild, and resume its former weight and properties which it possessed before calcination. But if it be

precipitated from the water by means of some substance which does not contain fixable air, but which is more strongly disposed than the earth to unite with the water, for instance, spirit of wine, the earth thus precipitated will be in the state of quicklime, that is, caustic, and soluble in water.

2. Quicklime unites with acids without effervescence, which is nothing else than an extrication of the fixable air, of which quicklime has been already deprived. It nevertheless saturates as much acid as it would have done if it had not been calcined.

3. Quicklime is more powerfully disposed to unite with fixable air than fixed or volatile alkalis, or magnesia. Hence, when treated with these substances, it takes from them their fixable air, and is itself rendered mild, and restored to its original weight and properties. Thus two drams of chalk, having been by calcination reduced to one dram and eight grains of quicklime, were thrown into a filtrated solution of an ounce of mild fixed alkali in two ounces of water, and digested during some time; by which the calcareous earth became mild, and weighed one dram and 58 gr. By means of magnesia, the calcareous earth may be precipitated from lime-water; and this earth is found to be mild, and to have deprived the magnesia of its fixable air. By depriving alkalis of their fixable air, quicklime renders them more caustic and solvent, for the same reason that itself is by this privation of air rendered more caustic and powerfully solvent. This increase of causticity and dissolving power is consistent with a general rule, namely, that the more simple or less compounded any body is, that is, the less its general tendency to union is satisfied, the more disposed it is to unite with or dissolve other substances.

4. Quicklime has a disposition to unite with sulphur, with which it forms a hepar of sulphur, similar to that made by sulphur united with an alkali, and, like this, soluble in water. It is also disposed to unite with oils and with animal and vegetable matters, with respect to which it discovers a caustic and corrosive property.

5. Quicklime mixed with sand forms a mass which hardens, and is used as a cement or mortar.

All these properties of quicklime have been the objects of consideration to the chemists and philosophers; who have, as usual, been divided in their opinions on the subject. The evident resemblance of the action of quicklime to fire, has given occasion for one party to derive all the active properties of this substance from fire; while, on the other hand, its want of heat, and incapacity of setting bodies on fire, unless by an accession of water, were objections altogether insurmountable. On the other hand, those who denied the materiality of fire, and affirmed that it consists only in a motion mechanically produced among the particles of bodies, were altogether at a loss to show a reason why this motion, or any thing resembling it, should continue perhaps for months after the exciting cause is taken away. To remove this difficulty, some have had recourse to the action of a latent acid communicated to the quicklime by the fire; and which one chemist (Mr Meyer) has distinguished by the name of *acidum pingue*. But on this hypothesis it may be remarked in the first place, that the action of acids is as difficult to be explained as that of fire; and, in the second place, that as all substances, by calcination into quicklime, lose considerably of their weight,

Quicklime. weight, it seems very improbable that they should acquire an acid or any other substance which could increase their weight. Besides, from the experiments of Dr Black, it appears that the diminution of weight in calcareous substances is owing to their parting with a quantity of fixed air, the weight of which is much more considerable than that of any moisture or fatty matter they contain. The loss of this fixed air is now also universally allowed to be the reason of the causticity of the quicklime, as its superior attraction for fixed air is looked upon to be the reason why it renders fixed and volatile alkalis caustic like itself. The only question therefore can be, By what means are the calcareous earths deprived of their fixed air? To this question the answer is evident, namely, that the action of the fire expels the fixed air; and if this is the case, it is evident, that to this action of fire, continued, the caustic properties of the lime are owing.

We come now to the discussion of the question, Whether quicklime is to be considered as a pure earth, or a combination of it with something else?—Most of the chemists, since the discovery of fixed air, have been inclined to think that quicklime is a pure earth uncombined with any thing else, and that it approaches more nearly to the state of elementary earth than any other. But this opinion seems not to have a solid foundation; for there are other earths, such as the basis of alum, which as far as they can be examined by us, are equally pure with quicklime, and yet discover not the smallest causticity, even after the most violent calcination. Besides, from the property which quicklime has of depriving alkaline salts of their fixed air, we may learn, that there exists in it, when kept by itself, a certain principle which prevents it from absorbing again the fixed air, with which it was once so closely united, except in certain circumstances. It is well known, that fixed alkalis, as well as those which are volatile, will absorb fixed air from the common atmosphere; and hence, tho' they are prepared in the most caustic state, they will in a very short time become mild by an exposure to the atmosphere; nay, it requires no small degree of care to prevent the atmosphere from having as much access to them as is necessary to change them from a caustic to a mild state. Now, as these substances thus attract the fixed air from the atmosphere, it thence appears that the atmosphere parts very readily with the fixed air which it contains. The quicklime, however, though it has a greater attraction for fixed air than the alkalis, yet does not become near so soon mild from exposure to the air as the alkalis which have less attraction than itself. Hence the necessary inference must be, that quicklime, after being once calcined, instead of attracting, repels fixed air, unless it is placed in certain circumstances, wherein the repelling power is destroyed, and the attractive power again manifests itself. Now it is manifest, that the power which originally repelled the fixed air was the action of fire; and consequently, while the quicklime refuses to attract fixed air, we must conclude that it is the same action which prevents the union. Quicklime therefore is not a pure earth, but a combination of a pure earth with fire; just as chalk, or limestone uncalcined, is not a pure earth, but a combination of a pure earth with fixed air. In all chemical trials, then, where quicklime is used, the double elective attraction will manifest itself as much as in a

combination of different salts, metals, and acids. Thus **Quicklime.** when water is poured on quicklime, the attraction between that element and earth is stronger than the attraction between earth and fire. The consequence is, that the water expels the fire, just as vitriolic acid poured upon sea-salt expels the marine acid. The fire, then, having nothing with which it can form a chemical combination, becomes sensible to the touch, first making the lime very hot, and then gradually dissipating in the atmosphere. However, as the water combines with the earth but in very small quantity, it can only expel the fire from that quantity with which it does combine; and consequently the lime still retains its caustic quality, though in a degree somewhat milder than what it was originally. We must also consider, that water itself has a considerable attraction for fire as well as for earth; and the consequence of this must be, that part of the lime will be dissolved in the water, if more of that element is added than what the earth can absorb without losing the form of a dry powder. Hence the origin of lime-water, which is only a small quantity of lime in its caustic state dissolved in a large quantity of water. This dissolution is owing to the double attraction of fire to earth and water; for as long as the water can admit the calcined earth to that intimate union with itself which is called a *chemical combination*, the earth must still retain all the causticity which the fire gives it, and dissolve in the water. When the earth is in too large quantity to be thus combined with the water, the latter is only absorbed into the pores of the earth, where by its bulk it splits the stone or calcined matter all to pieces, and reduces it to an impalpable powder, expelling a proportionable quantity of fire from those pores which it now occupies. The water, however, is capable of radically dissolving but a very small portion of calcined earth: and therefore the same quantity of quicklime will serve for preparing lime-water a great number of times over; but at last a large quantity is left, which seems to be quite inert, and has lost the properties of quicklime. Those who have tried the experiment of lixiviating lime with fresh quantities of water till it ceases to be soluble, have fixed the proportion of soluble matter in the lime at about one-third of the whole; but from Dr Black's experiments it appears that quicklime may all be dissolved in water at once, provided the water is in sufficient quantity. Its inactivity, therefore, after repeated affusions of water, must be owing to some change produced by the water; but whether this is owing to an absorption of all the fire it contained by the great quantity of water, or to a supply of fixed air given by the water, has not yet been determined by an experiment.

If, instead of pouring cold water upon quicklime, we pour that which is already heated, the absorption is much less complete; because the water, having already a superfluous quantity of heat, is resisted by that which is contained in the quicklime in a latent state; and hence it is a general observation, that hot water is less proper for slaking lime than cold. But if we pour on any acid upon quicklime which contains a great quantity of fire in a latent state, and has likewise a violent attraction for the earth, a much greater degree of heat is produced than with simple water. With the vitriolic acid, indeed, this is not so well perceived, if the com-

Quicklime mon calcaareous earths are made use of; because their insolubility in this acid diminishes its effect: but if, instead of these earths; we take magnesia newly calcined, the heat is so great, that the aqueous vapour, not having time to evaporate slowly, is driven off with a considerable explosion. If the common calcaareous earths, well calcined, are dissolved in the nitrous acid, a most violent degree of heat is produced; more indeed than in any other case where a liquid is concerned: for the nitrous acid itself contains a great deal of latent heat; the quicklime does the same; and by the intimate union of the earth with the acid, all this latent heat, at least a great part of it, both in the quicklime and spirit of nitre, is displaced, and attacks the aqueous fluid, as being nearest to it; from whence it is dissipated in the air, or absorbed by the neighbouring substances. The same thing happens, only in a less degree, when the marine acid is employed.

When quicklime is mixed with a solution of mild alkali, a double decomposition, and two new compositions, take place. The quicklime may be considered as a combination of earth and fire, while the alkali in the present case acts as a combination of salt and air. These two substances, therefore, are no sooner put into such circumstances as enable them to act on each other, than the quicklime attracts the air from the alkali, and gives its own fire in exchange, which the alkali takes up, and thus rendered caustic, while the quicklime becomes mild. Nevertheless, though the alkali here seems to have the greater attraction for fire, and the quicklime for air; yet it appears that the alkali is by no means capable of keeping the fire which it has imbibed for any length of time: for no sooner is it exposed to the action of the air, than it parts with the fire which it had imbibed, regains its air, and becomes mild. This, however in all probability is owing to its extreme solubility in water while in a caustic state; for quicklime itself, when dissolved in water very easily regains its fixed air, nay even more than it contains in a natural state. See the article SALT.

On the whole, then, the properties of quicklime may be explained in a very easy manner on Dr Black's principle of latent heat. That heat consists in a latent state in quicklime, as well as in vapour, we have incontestable proofs; because, in all cases where quicklime changes its nature and becomes more mild, a degree of heat is produced, and which is always proportionable to the change made on the quicklime. In the making of quicklime, therefore, the air is expelled, and a proportional quantity of fire enters; in dissolving it in an acid, slaking, &c. an acid, air, or water, expels part of the heat, which then becomes sensible. By long exposure to the air, the heat gradually evaporates; the fixed air resumes its place; and the quicklime being thus increased in bulk, embraces those bodies very closely which lie nearest to it; inasmuch that, when mixed with sand and stones, it will harden with them almost into the solidity of a rock (see CEMENT and MORTAR). When mixed with animal or vegetable substances, it destroys or decomposes them, both by the action of its internal heat, and by its attraction for a certain acid contained in the animal substances, and an oily matter in the vegetables; and hence its property of burning cloth, though its attraction for the oily

matter just mentioned makes it an excellent whitener **Quicksilver** when properly applied. See BLEACHING.

QUICKSILVER, or MERCURY, one of the perfect metals, and so fusible that it cannot be reduced to a solid state but by the most intense degree of cold, scarcely, if at all, under 40° below 0 of Fahrenheit's thermometer. See CONGELATION. For the method of extracting quicksilver from its ore, &c. see METALLURGY, p. 454, and 475. For the various preparations, &c. from it, see CHEMISTRY Index at mercury and quicksilver, and PHARMACY Index at mercury and quicksilver. And for its use in medicine, see MEDICINE, n° 350, and MERCURY.

It is found, 1. Native, as in the mines of India, Friuli, Lower Austria, Deux Ponts, &c. flowing through beds of stone, and collecting in the clefts or cavities of rocks. In these mines, however, Mr Kirwan is of opinion that it is mixed with some other metal, as the globules into which it is divided are not perfectly spherical. In Sweden and Germany it has been found united to silver in form of a hard and somewhat brittle amalgam. It has also been observed visibly diffused through masses of clay or stone, of a white, red, or blue colour, and very heavy in Spain and Idria; and in Sicily in beds of chalk.

Mines of quicksilver, however, are very rare, inasmuch that, according to the calculations of Hoffman, there is 50 times more gold got every year out of the mines than mercury and its ores. But Dr Lewis, in his notes upon Newmann, says, that Cramer suspects that Hoffman only meant five times instead of 50; but neither the Latin nor the English edition of this author expresses any such thought; on the contrary, he adopts the same opinion; and only adds, that mercury is much more frequently met with than is commonly believed; but being so volatile in the fire, it often flies off in the roasting of ores, and escapes the attention of metallurgists.

According to Newmann, the mines of Idria have produced at the rate of 231,778 pounds weight of mercury per annum; but those of Almaden in Spain produce much more. The chemists of Dijon inform us, that their annual produce is five or six thousand quintals, or between five and six hundred thousand pounds weight. In the year 1717 there were upwards of 2,500,000 pounds of quicksilver sent from them to Mexico, for the amalgamation of the gold and silver ores of that country.

At Guacanavelica in Brasil the annual produce of the mines, according to Bomare, amounts to one million of pounds, which are carried over land to Lima, thence to Arica, and lastly to Potosi for the same purpose.

Besides these mines there are others in Brasil near Villa Rica, where such a quantity of cinnabar and native running mercury are found near the surface of the earth, that the black slaves often collect it in good quantities, and sell it for a trifling price to the apothecaries; but none of these mines have ever been worked or taken notice of by the owners. Gold naturally amalgamated with mercury is likewise met with in the neighbourhood of that place; and it is said that almost all the gold mines of that country are worked out by simply washing them out with running water, after reducing into powder the hard ores, which are sometimes imbedded in quartzose and rocky matrices.

In the duchy of Deux Ponts and in the Lower Austria

Quick-
silver.

Idria the quicksilver flows from a schistose or stony matrix, and is probably, says Mr Kirwan, mixed with some other metal, as its globules are not perfectly spherical. The mines of Friuli are all in similar beds or strata. The metal is likewise found visibly diffused through masses of clay or very heavy stone, of a white, red, or blue colour; of which last kind are the mines of Spain, some of Idria, and of Sicily. Mascagni found fluid quicksilver, as well as native cinnabar and mineral ethiops, near the lake of Travale in the duchy of Sienna; but the quantity was so small as not to be worth the expence of working. On the other hand, the following mines afford profits to the owners after clearing all expences, viz. those at Kremnitz in Hungary; at Horowitz in Bohemia; Zorge in Saxony; Wolfstein, Stahlberg, and Moeschfeld in the Palatinate. Mercury is also brought from Japan in the East Indies; but the greatest part of what is sold in Europe as Japan cinnabar is said to be manufactured in Holland.

Lemery, Pomet, and others, lay down some external marks by which we may distinguish those places where there are mines of quicksilver, viz. thick vapours like clouds arising in the months of April and May; the plants being much larger and greener than in other places: the trees seldom bearing flowers or fruit, and putting forth their leaves more slowly than in other places; but, according to Neumann, these marks are far from being certain. They are not met with in all places where there is quicksilver, and are observed in places where there is none. Abundance of these cloudy exhalations are met with in the Hartz forest in Germany, though no mercury has ever been found there; to which we may add, that though vast quantities of mercurial ores are found at Almaden in Spain, none of the abovementioned indications are there to be met with.

Native mercury was formerly sought from the mines of Idria with great avidity by the alchemists for the purpose of making gold; and others have showed as ridiculous an attachment to the Hungarian cinnabar, supposing it to be impregnated with gold; nay, we are informed by Neumann, that not only the cinnabar, antimony, and copper of Hungary, but even the vine trees of that country were thought to be impregnated with the precious metal. Not many years ago a French chemist advertised that he had obtained a considerable quantity of gold from the ashes of vine twigs and stems, as well as of the garden soil where they grew; but the falsehood of these assertions was demonstrated by the count de Lauragais to the satisfaction of the Royal Academy of Sciences.

The reduction of mercury into a solid state, so that it might be employed like silver, was another favourite alchemical pursuit. But all processes and operations of this kind, says Neumann, if they have mercury in them, are no other than hard amalgams. When melted lead or tin are just becoming consistent after fusion, if a stick be thrust into the metal, and the hole filled with quicksilver, as soon as the whole is cold, the mercury is found solid. Macquer informs us, that mercury becomes equally solid by being exposed to the fumes of lead. Maurice Hoffman, as quoted by Neumann, even gives a process for reducing mercury, thus coagulated, to a state of malleability, viz. by repeatedly melting and quenching it in lintseed oil. Thus, he

Vol. XV.

tells us, we obtain a metal which can be formed into rings and other utensils. But here the mercury is entirely dissipated by the repeated fusions, and nothing but the original lead is left. Wallerius, after mentioning strong soap-leys, or caustic lixivium, and some other liquors proper for fixing quicksilver, tells us, that by means of a certain gradatory water, the composition of which he learned from Crenling *de Aureo Vellere*, he could make a coagulum of mercury whenever he pleased, of such consistency that great part of it would resist cupellation; but what this gradatory water was, he has not thought proper to lay before the public.

2. Native precipitate *per se*, in which the metal is mineralized by aerial acid. This was lately found in Idria, in hard compact masses of a brownish red colour and granular texture, mixed with some globules of native mercury. An hundred parts of it afford 91 of running mercury.

Various little globules of mercury were contained in this ore, which are rendered very visible by being heated, but are soon reabsorbed by cooling. On exposing it to the fire in an iron spoon, the red colour soon became more vivid, but turned yellowish on cooling. Distilled in a pneumoniac apparatus, a quantity of dephlogisticated air was produced, though less by one fourth than what should have been produced by an equal quantity of cinnabar. On distilling an ounce of this ore in a glass retort, a little yellow powder was left, which weighed a fourth part of a grain, and stained the bottom of the retort in a manner similar to what is done by the calx of silver to white glass in similar circumstances. On cupelling this powder with 144 grains of lead wrapped up in paper, the increased weight of the lead over that of the test of comparison showed that the calx was reduced into its metallic state of silver and mixed with that of lead.

3. Mineralised by the vitriolic and marine acids. This kind of ore was first discovered in the year 1776, at Obermoschal in the duchy of Deux Ponts. It has a spar-like appearance, and is either bright and white, or yellow or black, and mixed with cinnabar in a stony matrix. The native marine salt of mercury is in the state of corrosive sublimate.

4. Native cinnabar, in which the metal is mineralised by sulphur. This is of different shades from a yellowish to a deep red; and is found either pure in hard friable masses, either shapeless or crystallised in cubes, and sometimes transparent, or intermixed with clay or stone, or interspersed through the ores of other metals, particularly those of silver, copper, or martial pyrites. Its texture is either radiated, striated, scaly, or granular. An hundred parts of cinnabar contain about 80 of mercury and 20 of sulphur; but artificial cinnabar contains a little more sulphur, and hence its colour is darker. Its specific gravity is about 7.000; it sublimes in close vessels, and is decomposed and volatilized in open ones. It is found in the duchy of Deux Ponts, in the Palatinate, in Hungary, Friuli, and Almaden in Spain, and in south America, especially at Guancavelica in Peru. It is sometimes compact, and sometimes found in transparent, ruby-coloured crystals, and often in a kind of scales or flattened laminae. It is called native vermilion, and cinnabar in flowers, when it is in the form of a very bright red powder. It is also found in different earths, in selenite mixed with iron, with pyrites,

5 D

and

Quick-
silver.

Quick-
silver.

and with sulphur. Mr Fourcroy enumerates the following varieties: 1. Transparent cinnabar, red and crystallized in very short triangular prisms, terminated by triangular pyramids. 2. Transparent red cinnabar, in octohedral crystals, consisting of two triangular pyramids united at their bases and truncated. 3. Solid compact cinnabar, of a brown or bright red; it is sometimes foliated. 4. Red cinnabar distributed in striæ, on a stony matrix, or on solid cinnabar. It is sometimes composed of needles like cobalt. 5. Cinnabar in flowers, or native vermillion. It is of a bright red colour, and satin appearance, adhering to different matrices, in form of a very fine powder. It is sometimes crystallized in very small needles, and then greatly resembles the foregoing.

The finer coloured ores of mercury are never worked for extracting the metal, but used entirely as pigments; but they have been very injudiciously preferred for medicinal uses to the more pure factitious cinnabars; for we seldom meet with any native cinnabar that has not some earthy or stony matter intermixed with it, nor with two pieces that perfectly agree. There are three varieties principally distinguished in the shops; viz. 1. Cinnabar in masses weighing from one to six ounces or more. 2. In grains, prepared by breaking the worse coloured masses, and picking out the best coloured bits. 3. Washed cinnabar, prepared by washing over the lighter impurities that are to be found in it. No native cinnabar should ever be employed in medicine without being previously purified by sublimation. Neumann informs us that he never met with any native cinnabar which did not leave a grey ash or sand, amounting, among different parcels, from one ninth to one fifth of the mineral employed. The residuum had no gold in it, though the colour of its solution and precipitate gave some expectation of it at first sight.

Neumann remarks, that though vitriolic acid forms with mercury a lively yellow concrete, viz. turbith mineral, and with the inflammable principle a yellow sulphur; and though sulphur itself forms with mercury a beautiful red cinnabar; yet the same vitriolic acid destroys the red colour entirely, rendering it as white as milk. This change is not immediately produced on common cinnabar by the vitriolic acid; but, on being digested over a strong sand heat in a glass cup, it soon becomes as white as cream; and the vitriolic acid takes the form of a strong sulphureous and volatile vapour, very suffocating and corrosive; emitting very piercing fumes for some time, which turned the paper that covered it black, and destroyed its texture.

5. Black ore of mercury, in which the metal is mineralized by sulphur and copper. This is of a blackish grey colour, a glassy texture, brittle, heavy, and decrepitating strongly when heated. It is found at Mufchel Lansberg. An ore of this kind is also found in the duchy of Deux Ponts. In the sulphur of Idria a black cinnabar is likewise said to be found, which retains its colour in sublimation; but this is not yet sufficiently confirmed, though it is too bold an assertion of Dr J. R. Forster that no such cinnabar has ever been found. He adds, that a certain learned man thought he had discovered some near the copper ores at Lautenberg; but that it proved to be a red copper calx, which is still to be met with in that place.

6. Pyritous mercurial ore was brought from Dauphiny by Mr Montigny in 1768. It is grey, whitish, and friable. An hundred parts yielded one of mercury, one half of silver, the remainder being iron, cobalt, sulphur, and arsenic.

7. An ore of mercury, in which the metal is mineralized with iron by sulphur, is mentioned by Sir Torbern Bergman in his *Sciagraphia*, sect. 177. He says that it is doubtful whether this does not belong to the species of cinnabar, as the iron is perhaps only mechanically diffused thereon. Mr Mongez informs us, that there are but few instances of cinnabar in which iron is not found in its calcined form, though, in the act of the ore being reduced, it passes to its metallic state, and becomes capable of being acted upon by the loadstone.

Another pyritous ore of cinnabar was found at Menidot, near St Lo in Lower Normandy. It consisted of differently sized grains of a red brown colour: they had a vitriolic taste and sulphureous smell. Pyritous ores of this kind are likewise found at Almaden in Spain, and at Stahlberg in the Palatinate. The cinnabarc pyrites of this last place are of a dodecaedral form.

8. Mr Gellert informs us, that an ore of quicksilver is met with in Idria, where the mercury lies in an earth or stone, as if it were in a dead form; and has the appearance of a red-brown iron-stone, but much heavier. It contains from three quarters to seven-eighths of the purest mercury, leaving after distillation a very black strong earth, giving also some marks of cinnabar. For, as we do not know the ultimate divisibility of mercury, we cannot justly determine the point of its fluidity, although its globules may be no more discernible.

The *liver-ore*, which is most common in Idria, and has its name from its colour, resembles an indurated iron-clay; but its weight discovers it to have metallic contents. An hundred weight of it sometimes yields 80 pounds of quicksilver.

The *brand-erz*, or burning ore of the Germans, likewise belongs to this species. It may be lighted at a candle, and yields from 9 to 50 pounds of metal in the 100.

9. Dr Gmelin informs us, that cinnabar mixed with arsenic or realgar is said to be found in Japan; and that at Morsfield the cinnabar and white calx of arsenic present themselves in the same rock.

10. Besides the ores already mentioned, we sometimes meet with quicksilver natively amalgamated with gold, silver, and other metals. This is taken notice of by Bergman; and from the authorities of Monet and Prof. Gmelin, Mr Kirwan informs us, that in Sweden and Germany this metal has been found united to silver in an hard brittle amalgam. M. de L'Isle had a specimen of this ore from Germany; which, as M. Mongez informs us, is imbedded in a quartzose mass, and mixed with cinnabar. A specimen brought from the mine called *Carolina*, in a crystalline form, was deposited in the royal cabinet at the king's garden at Paris. M. de L'Isle likewise informs us, that a specimen of native gold was brought from Hungary, which, according to Cronstedt, was probably an amalgam of mercury and gold. It is composed of quadrangular prisms, of a greyish yellow colour, and brittle texture. Neumann likewise observes, that sometimes a mineral, containing

Quick-
silver.

Quick-
silver.

containing gold or silver, is met with among mercurial ores, though very rarely.

These natural amalgams account for the great specific gravity of some kinds of quicksilver. This may proceed from a natural mixture of gold, though, according to Boerhaave, it may also arise from its being redistilled a great number of times. By a similar mode of reasoning we may conclude, that the smallest specific gravities of quicksilver proceed from its amalgamation with silver, lead, and other metals or semimetals, which in spite of repeated distillations may still preserve their union with it; for Dr Boerhaave informs us that he could not, by any number of distillations, free mercury perfectly either from tin or lead.

M. Magellan, in his notes on Cronstedt's Mineralogy, says, "That mercury is many times found amalgamated with lead, is easily evinced by the process of M. Grosse, mentioned by Macquer in his elements of Chemistry, where the method of extracting mercury from some solutions of lead is described; but the same Macquer, in his Chemical Dictionary, positively affirms, that, though Beccher and Kunckel have both given other processes for extracting mercury from lead, and though the method pointed out by M. Grosse is easier than the others, nevertheless it does not succeed if the lead be quite pure without any amalgamation with mercury. And Boerhaave has expressly made the same assertion, complaining of those authors who affirm the contrary." Dr Black, however, seems to be of a different opinion; and, in his public course of lectures, teaches that, "by some processes of the more difficult kind, mercury may be extracted from lead;" though he cautions us, at the same time, not to infer from this, or any other chemical process, the possibility of the transmutation of metals.

Mercury is not in any way altered by the action of light. Its dilatation by heat is extremely regular, as has lately been shown, in a very great variety of experiments, by Dr Adair Crawford; for which reason it is used as the measure of heat, and thermometers are usually filled with this metal. When opposed to the heat of about 600° of Fahrenheit, it boils and is dispersed in an invisible fume; which, however, has been observed to have the elasticity of the steam of water, and to burst an iron box in which it was attempted to confine it. If it be made to boil in a close vessel fitted with a proper apparatus, it will all come over in its proper form, and leave any fixed matter it might contain in the retort. This affords an easy method of purifying it from the base metals with which it is frequently adulterated; though even in this way it is necessary to raise the fire cautiously, or a part of the fixed metal will be carried up along with the mercury. And even with all the care that can be taken, it has been found impossible, as has been already said, to free it perfectly from a mixture of the base metals by any number of distillations.

By a very great number of distillations, however, it was said that some change might be made upon this metal; and that it became not only purer, but specifically *heavier*, by such an operation. Boerhaave, after making it undergo this operation 511 times, found some difference; but three years after, in a Memoir inserted in the Philosophical Transactions for 1736, he acknowledged, that, on repeating the operation 877 times, its

specific gravity, as shown by Dr Gravefande's nice hydrostatic balance, appeared to be no more than 13.500 to distilled water.

"Boerhaave died (says Mr Magellan in his Notes on Cronstedt's Mineralogy) two years after, on the 23d of September 1738; and left his papers to his two nephews, Herman, who died the 7th of October 1753, and Kaw, who died five years after. On their deaths the manuscripts fell into the hands of Charles Frederick Kruse physician to the Emperor of Russia. This gentleman published a short extract from Boerhaave's Diary in the ninth volume of the *Novi Commentarii* of the Imperial Academy of Petersburg, of which the following are the results.

"The specific gravity of the purest gold to that of distilled water is	19,024
That of mercury distilled once in a retort	13,570
Distilled 1009 times	13,590
Once from its amalgam with gold	13,550
750 times with the same amalgam	13,520
877 times from the same	13,500
Once from its amalgam with silver	13,550
217 times from the same amalgam	13,500

"It is evident, therefore, by these facts, that mercury does not acquire any additional increase to its specific gravity by the mere repetition of simple distillations, nor by its amalgamations with gold or silver, provided it be afterwards properly saturated by fire."

It is certain, however, that there are very considerable differences in the specific gravity of different specimens of quicksilver; and authors have by no means agreed in fixing the standard.—Bergman states it at 14.110; and Muschenbroek asserts that such was the specific gravity of Boerhaave's quicksilver that had been distilled 511 times; but some modern authors, among whom is M. Fourcroy, state the specific gravity of this metal at no more than 13.000. Modern experiments, however, show that it is generally about 13.500 or 13.600. "This (says Mr Magellan) I am informed was the mean specific gravity found by the late Lord Cavendish, after the repeated and nice trials he made upon 50 different specimens of quicksilver, on which he employed all his industry and attention to determine this point.

"The hydrostatical experiments I lately undertook of this kind upon ten different specimens of mercury, two of which were revived from natural and artificial cinnabar by the operator of Mr Kirwan, confirmed me in the same opinion.

"The temperature of the atmosphere was nearly the mean, viz. at the 50th degree of Fahrenheit's thermometer; and the scales employed were so nice, that they turned with the hundredth part of a grain when loaded with four pounds weight.—The method made use of to ascertain these specific gravities is the easiest of all. A phial of white glass with a ground stopple was counter-balanced with lead or other matter in a nice pair of scales. The substance to be tried was introduced into the phial and weighed together, and the weight we suppose = *a*. The remaining space of the phial being then filled with distilled water, we suppose the weight now to be = *b*. Lastly, the phial was filled with distilled water, and the weight supposed = *c*. It is evident,

Quick-
silver.

Quick-
silver.

dent, that $b - a = d$, the quantity of water in the second operation; $c - d = e$, the water whose bulk is equal to that of the substance; and that $\frac{a}{e}$ is the specific

gravity sought for.—Particular care was taken that no bubble of air remained in the inside. For this purpose a very small groove was made with a file on the inside of the glass stopper; and this was introduced sidewise without admitting any air, leaving the superfluous water to rush out.

“The greatest specific gravity of any of those specimens was 13.620, and the least 13.450. The heaviest was neither of the two that had been distilled from cinabar, but a common quicksilver bought at Apothecaries Hall, London; and the lightest was taken from a barometer of the best and dearest kind made by one of the most reputed instrument-makers in England.

“The most obvious cause of this difference of specific gravity in quicksilver seems to be its mixture or amalgamation with other metals. Certainly, when united to gold, its gravity must of course be specifically augmented: on the contrary, it must be lessened when united with any other metal, platina only excepted; and the same must be the case whether water or any other moisture is mixed with it; for in such a case the metal will be found heavier after evaporation. A simple boiling of the quicksilver over the fire in an open vessel will completely free it from this mixture; and no careful maker of experiments should neglect the preparation before he undertakes to employ mercury in any process, or for any purpose of the philosophic kind. The boiling must be continued for 20 or 30 minutes in order to expel the whole moisture.

Another cause by which the specific gravity of quicksilver becomes subject to alteration is the difference of temperature of the atmosphere at the time of making the experiment. Nor is it quicksilver alone, but every other substance whose specific gravity is affected by this cause in a greater or lesser degree; inasmuch that Mr Magellan does not hesitate to pronounce the labours of all those who have undertaken to compose tables of specific gravities, without regard to this circumstance, to be, it not entirely useless, at least incapable of affording proper satisfaction in the nice inquiries that depend on this knowledge.

In Eichenmid's table of specific gravities it is asserted, that a cubic inch of mercury in summer weighs seven ounces, one gros, 66 grains; but in winter it weighs 20 grains more: the whole weight then being seven ounces, two gros, 14 grains (allowing 72 grains to the gros). This, however, leaves the matter almost in as great uncertainty as before; the summer and winter temperature being widely different in different places, and very often even in the same place. Unless therefore the temperature of the air is attended to at every experiment in taking the specific gravity of any substance whatever, there can be no certainty of the result.

Quicksilver always feels cold when touched in the common temperature of the atmosphere. Our sensations, according to Fourcroy, deceive us in this case, for a thermometer dipped in quicksilver always shows the common temperature. “The great continuity of contact between the live skin and numerous metallic particles in an equal space, and which are proportional to its great specific gravity, necessarily produces a strong-

er sensation of its own temperature, this being always much less than that of a living body; and the multiplicity of these points of contact being all at once applied to this organ of sensation, must be more powerfully felt than whenever we touch any other matter that is lighter in itself, or of a less density.”

Notwithstanding this apparent coldness, however, quicksilver, when exposed to the same degree of heat, and in the same circumstances with various other substances, soon becomes hotter to the touch than any of them. “The fundamental principle of this (says Mr Magellan) consists in the small quantity of specific fire, or the less capacity which mercury is endowed with of receiving heat. This is such, that, compared with the capacity of water for the same purpose, it is in the ratio of 0.033 to 100, as appears by the table of the quantities of specific fire contained in various bodies.—This table, published in Magellan's Essay on Elementary Fire, was grounded upon various important experiments and observations made by Mr Kirwan, in consequence of the new Theory of Fire discovered by Dr Crawford. Hence it follows, that if equal quantities of heat be communicated to equal quantities of water and mercury, the latter will have a temperature 30 times greater than that of the water; that is to say, in the inverse ratio of their respective capacities, or as 1 to 30 ($= 0.033 : 1.000$), in the same manner as it must happen, when equal measures of corn or of any fluid are thrown into vessels whose bottoms are as 30 to 1; for then their heights must necessarily be in their inverse ratio, viz. of 1 to 30, &c. See CHEMISTRY, n° 1225, &c.

Quicksilver does not appear to dissolve in water; but Fourcroy remarks, that physicians are in the practice of suspending a bag full of it in vermifuge ptisans during their ebullition, and that experience has evinced the good effects of it. Lemery asserts, that in this process there is no loss of weight; but this is denied by others. Fourcroy asserts, that this metal, rubbed between the fingers, emits a perceptible odour, though Magellan says he tried the experiment many times without success.

Fourcroy likewise asserts, that mercury when pure emits a phosphoric light by agitation, particularly in hot seasons. This phenomenon has certainly been observed in the mercury of the barometer; but its appearance on other occasions rests entirely on the authority of Mr Fourcroy. Even in the barometer it does not take place, unless the Torricellian vacuum be not perfectly made in the space at the top of the tube. Phials of glass nearly exhausted of air, and containing some quicksilver hermetically sealed up, will, on being shaken, produce as much light in the dark as is sufficient to show the hour on the dial-plate of a watch. But if a perfect vacuum be produced by nicely boiling the quicksilver within the glass, no appearance of this kind is to be perceived. The phenomenon is certainly of the electrical kind; and its not appearing in the perfect vacuum is owing to the difficulty there is in setting in motion any large quantity of electric matter by itself, which indeed can scarce be done without producing very violent effects. See *ELECTRICITY-Index*.

Mercury unites with all the metals and semimetals, excepting iron and regulus of antimony. These compounds are called *amalgams*; and Mr Machy has observed,

Quick-
silver.

Quick-
silver.

served, that in forming them a certain degree of cold is produced. He made the experiment by covering the ball of a thermometer with tin-foil, and then dipping it into quicksilver; upon which that in the thermometer fell some degrees: which agrees perfectly well with the doctrine of latent heat first discovered by Dr Black, as it shows that in this, as well as other cases, where a body passes from a solid into a fluid state, a degree of cold is produced.—The following observations on the amalgams of mercury with different metals are extracted from the Memoirs of the Academicians of Dijon.

1. The amalgam of gold and mercury crystallizes into quadrangular pyramids. Six ounces of mercury are retained by one of gold in this crystallization; but that with silver retains a third part more of quicksilver.

2. The amalgam with silver is likewise susceptible of crystallization, and assumes the form of a tree; every ounce of silver retaining eight of mercury. This amalgam, by means of the nitrous acid, well freed from the vitriolic by solution of silver in the same, forms that curious kind of vegetation mentioned in the article CHEMISTRY, n° 754, called *Arbor Dianæ*, or *Arbor Philosphorum*.—The following is recommended by Mr Magellan as the shortest process:

“Dissolve 228 grains of silver, and half as much quicksilver, in pure nitrous acid. Add to the solution, when made, five ounces (of 576 grains each) of distilled water. Put this solution into a spherical vessel of white glass, at the bottom of which must already be put 432 grains of an amalgam of silver of the consistence of butter: let the vessel be kept in a quiet place, free from any shaking or external agitation; and at the end of some few hours the figure of a bush or tree of silver will be formed within the water of the glass vessel. The metals contained in the solution and in the amalgam attract each other, and a number of small tetrahedral crystals are formed, which lay hold at one another's end, and form the appearance of a vegetation.

3. Copper is amalgamated with mercury with great difficulty, and only by mixing blue vitriol with mercury and water in an iron retort over the fire. The acid then attacks the vessel, and the copper is precipitated in a metallic state, which, by stirring it with an hot iron spatula, unites to the mercury, but does not crystallize.

4. Two ounces of melted lead poured on a pound of mercury produce a half fluid amalgam, which being decanted gives some crystals like those of silver. One ounce of these crystals retains an ounce and an half of mercury.

5. The amalgam of tin crystallizes into thin shining lamellæ, with polygonous cavities between one another. Two ounces of tin retain six of mercury in this crystallization.

6. Mercury amalgamates with bismuth by means of heat, and produces crystals of an octohedral form, and lamellated triangles and hexagons. They are black on the upper surface, and shining underneath. In this crystallization the bismuth retains double its weight of mercury.

7. Zinc, in fusion, poured upon mercury, produces a crackling noise resembling that produced by a hot body thrown into boiling water. It crystallizes very well into lamellated hexagonal figures, leaving cavities among themselves. One ounce of zinc retains two and a half of mercury in this crystallization.

8. *Quicksilver* does not amalgamate with arsenic, except by heat, and then only in very small quantity. This metal answers very important purposes both in medicine and the arts. Though it has no perceptible taste, it produces very remarkable effects on the stomach and intestines of animals, as well as on the surface of the skin. Insects and worms are extremely sensible of this effect, and the metal, almost in any state, is exceedingly pernicious to them. Physicians, therefore, employ it as an excellent vermifuge (see MEDICINE, p. 341.), and it is likewise one of the most powerful remedies in the materia medica for many obstinate disorders besides those of the venereal kind, in which its efficacy has long been celebrated. “Even the most virulent product of mercury (says Mr Magellan), known by the name of sublimate corrosive, which is the most violent poison, is often taken internally in very minute doses, under the direction of skilful physicians, and produces the most happy effects in a great variety of cases even of the most desperate kind. This is a fact which I have experienced myself, in a dreadful scorbutic complaint which I suffered for above four years, with restless and violent pains in the eyes and head. None of the most able physicians in London and Paris I consulted afforded me any effectual relief, till I had the good fortune to consult Mr Sacre surgeon-oculist at Antwerp. His prescription consisted of three grains of sublimate dissolved in a pint of common proof spirit. The dose consisted in taking every morning two spoonfuls of it in a pint of new milk. In less than two months I began to feel relief; and in three months time was completely cured. The first methodical practice of this remedy was communicated to the celebrated Van Swieten, first physician to the Emperor's court, by the late Dr A. R. Sanches, then chief physician to the court of Petersburg, as appears by the last volume of the Commentaries of the same Van Swieten, published in 1772. This volume was published after the author's death; but he had enjoyed during his life the glory of being the author of this wonderful remedy, which continues to bear his name among the ignorant and inaccurate physicians of our times.”

But whatever uses this salt may be put to when taken in small quantities, it is certainly not less violent than arsenic itself, if taken in a large dose; and the danger is the greater, on account of the difficult solution of the salt, which requires for this purpose 19 times its weight of water. Alkaline salts, however, prove a very effectual antidote, and will instantly relieve the symptoms; but, on account of the insolubility of the poisonous salt, the disorders occasioned by it soon return, and require a repetition of the same remedy. In cases where alkaline salts are not immediately at hand, soap dissolved in water will answer the same purpose; or if this also should not be instantly procurable, chalk, lime, spirit of hartshorn, or magnesia alba, might be used with good effect.

Quicksilver is employed in Chili and Peru to extract gold and silver, when native, from the earthy matters with which they are mixed. The principle on which this method is founded is the strong mutual attraction betwixt mercury and the precious metals. By reason of this the smallest particles either of gold or silver form an amalgam with the mercury, part of which is strained off, and the remainder either separated by dis-

solution

Quick-
silver.

match.

Quid
||
Quietists.

distillation in iron retorts, or by a kind of distillation *per d'scensum*; putting it in a kind of metallic sieve over a vessel of water, to receive the mercury, which is driven down by a fire lighted in a vessel above the amalgam.

The amalgam with gold serves also to gild copper or silver, so that they appear as if made of solid gold.—For this purpose the pieces are to be well cleaned, and then dipped in a weak aqua fortis; then in a nitrous solution of quicksilver, which covers them with a kind of silvering. After this the amalgam of gold is very equally spread over them; which being done, the piece is exposed to a heat sufficient to volatilize the quicksilver, and the gold is then left strongly adhering to the metal. The only use to which the amalgam of mercury with lead has hitherto been applied, is the luting glass vessels in which specimens of natural history are to be preserved in spirit of wine. For this it is more proper than any other substance, having an excellent effect in preventing evaporation. The amalgam of tin is commonly employed in making looking-glasses or mirrors. The thin sheet of tin is laid down on a large flat table of stone; a proper quantity of mercury, in which some tin has already been dissolved to prevent it from destroying the tin sheet, is rubbed over with a bunch of cloth like a flat bung, and the glass carefully slid upon it from one end to the other, in such a manner that the dirty crust of the quicksilver is driven off before its edge; and the glass is then loaded with weights all over: by inclining gradually the stone table, the superfluous mercury is discharged, and in a few hours both cohere together. This amalgam is used for exciting the electricity of glass globes in the common electrical machines, but is said to be inferior in strength to that made with zinc.

Quicksilver heated by itself, with access of air, is by degrees converted into a red powder, improperly called *Mercurius precipitatus per se*. It consists of the calx of the metal united with the basis of dephlogisticated or pure air, which may be expelled from it again by a strong heat; and this was the first method by which Dr Priestley obtained this kind of air.

Mercury is not altered by the contact of air: It is only observed, that it becomes tarnished by the particles of dust which the air deposits; and from that circumstance mercury has been called the loadstone of dust.—Though all bodies have this property, it seems more remarkable in mercury than any other, on account of its great splendour; but it is not in the least changed by this circumstance, nothing more being necessary to restore it to its original brilliancy than filtration through a piece of shamoy leather.

The volatility of mercury prevents it from uniting with earths in the way of fusion; though M. Fourcroy is of opinion that its red calx, or precipitate *per se*, might perhaps fix in glasses, and colour them, as is observed in the calx of arsenic.

QUICK-MATCH, among artillery men, a kind of combustible preparation formed of three cotton strands drawn into length, and dipped in a boiling composition of white-wine vinegar, saltpetre, and mealed powder. After this immersion it is taken out hot, and laid in a trough where some mealed powder, moistened with spirits of wine, is thoroughly incorporated into the twists of the cotton, by rolling it about therein. Thus prepared, they are taken out separately,

and drawn through mealed powder; then hung upon a line and dried, by which they are fit for immediate service.

QUID PRO QUO, in law, *q. d.* "what for what," denotes the giving one thing of value for another; or the mutual consideration and performance of both parties to a contract.

QUID PRO QUO, or QUI PRO QUO, is also used in physic to express a mistake in the physician's bill, where *quid* is wrote for *quo*, i. e. one thing for another; or of the apothecary in reading *quid* for *quo*, and giving the patient the wrong medicine. Hence the term is in the general extended to all blunders or mistakes committed in medicine, either in the prescription, the preparation, or application of remedies.

QUIDDITY, QUIDDITAS, a barbarous term used in the schools for *essence*. The name is derived hence, that it is by the essence of a thing that it is *tale quid*, such a *quid*, or thing, and not another. Hence what is essential to a thing is said to be *quiddative*.

QUIETISTS, a religious sect, famous towards the close of the last century. They were so called from a kind of absolute rest and inaction, which they supposed the soul to be in when arrived at that state of perfection which they called the *unitive life*; in which state they imagined the soul wholly employed in contemplating its God, to whose influence it was entirely submissive; so that he could turn and drive it where and how he would. In this state, the soul no longer needs prayers, hymns, &c, being laid, as it were, in the bosom and between the arms of its God, in whom it is in a manner swallowed up.

Molinos, a Spanish priest, is the reputed author of Quietism; though the Illuminati in Spain had certainly taught something like it before. The sentiments of Molinos were contained in a book which he published at Rome in the year 1681, under the title of the *Spiritual Guide*; for which he was cast into prison in 1685, and where he publicly renounced the errors of which he was accused. This solemn recantation, however, was followed by a sentence of perpetual imprisonment, and he died in prison in the year 1696. Molinos had numerous disciples in Italy, Spain, France, and the Netherlands. One of the principal patrons and propagators of Quietism in France was Marie Bouviers de la Mothe Guyon, a woman of fashion, remarkable for goodness of heart and regularity of manners; but of an unsettled temper, and subject to be drawn away by the seduction of a warm and unbridled fancy. She derived all ideas of religion from the feelings of her own heart, and described its nature to others as she felt it herself. Accordingly, her religious sentiments made a great noise in the year 1687 and they were declared unsound, after accurate investigation, by several men of eminent piety and learning, and professedly confuted, in the year 1697, by the celebrated Bossuet. Hence arose a controversy of greater moment between the prelate last mentioned and Fenelon archbishop of Cambray, who seemed disposed to favour the system of Guyon, and who in 1697 published a book containing several of her tenets. Fenelon's book, by means of Bossuet, was condemned in the year 1699, by Innocent XII. and the sentence of condemnation was read by Fenelon himself at Cambray, who exhorted the people to respect and obey the papal decree, Not-

Quietists
||
Quills.

Notwithstanding this seeming acquiescence, the archbishop persisted to the end of his days in the sentiments, which, in obedience to the order of the pope, he retracted and condemned in a public manner.

A sect similar to this had appeared at Mount Athos in Thessaly, near the end of the 14th century, called *Hesychasts*, meaning the same with Quietists. They were a branch of the mystics, or those more perfect monks, who, by long and intense contemplation, endeavoured to arrive at a tranquillity of mind free from every degree of tumult and perturbation. In conformity to an ancient opinion of their principal doctors (who thought there was a celestial light concealed in the deepest retirements of the mind), they used to sit every day, during a certain space of time, in a solitary corner, with their eyes eagerly and immovably fixed upon the middle regions of the belly or navel; and boasted, that while they remained in this posture, they found, in effect, a divine light beaming forth from their soul, which diffused through their hearts inexpressible sensations of pleasure and delight. To such as inquired what kind of light this was, they replied, by way of illustration, that it was the glory of God, the same celestial radiance that surrounded Christ during his transfiguration on the Mount. Barlaam, a monk of Calabria, from whom the Barlaamites derived their denomination, styled the monks who adhered to this institution *Masaliens* and *Euchites*; and he gave them also the new name of *Umbiicani*. Gregory Palamas, archbishop of Thessalonica, defended their cause against Barlaam, who was condemned in a council held at Constantinople in the year 1341.—See *Fenelon's Max. des Saints*.

The Mahometans seem to be no strangers to quietism. They expound a passage in the 17th chapter of the Koran, viz. "O thou soul which art at rest, return unto thy Lord, &c." of a soul which, having, by pursuing the concatenation of natural causes, raised itself to the knowledge of that being which produced them, and exists of necessity, rests fully contented, and acquiesces in the knowledge, &c. of him, and in the contemplation of his perfection.

QUILLET (Claude), an eminent Latin poet of the 17th century, was born at Chinon, in Touraine, and practised physic there with reputation; but having declared against the pretended possession of the nuns of Loudun, in a manuscript treatise, the original of which was deposited in the library of the Sorbonne, he was obliged to retire into Italy, where he became secretary to the marshal d'Estrees, the French ambassador at Rome. In 1655 Quillet having published in Holland a Latin poem, entitled *Callipadia*, under the name of *Galvidius Lætus*, he there inserted some verses against the cardinal Mazarine and his family; but that cardinal making him some gentle reproaches, he retrenched what related to the cardinal in another edition, and dedicated it to him, Mazarine having, before it was printed, given him an abbey. He died in 1661, aged 59, after having given Menage all his writings, and 500 crowns to pay the expence of printing them; but the abbé took the money and papers, and published none of them. His *Callipadia*, or the art of getting beautiful children, has been translated into English verse.

QUILLS, the large feathers taken out of the end

of the wing of a goose, crow, &c. They are denominated from the order in which they are fixed in the wing; the second and third quills being the best for writing, as they have the largest and roundest barrels. Crow-quills are chiefly used for drawing. In order to harden a quill that is soft, thrust the barrel into hot ashes, stirring it till it is soft, and then taking it out, press it almost flat upon your knee with the back of a penknife, and afterwards reduce it to a roundness with your fingers. If you have a number to harden, set water and alum over the fire, and while it is boiling put in a handful of quills, the barrels only, for a minute, and then lay them by.

QUIN (James), a celebrated performer on the English stage, was born at London in 1693. He was intended for the bar; but preferring Shakespeare to the statutes at large, he on the death of his father, when it was necessary for him to do something for himself, appeared on the stage at Drury-lane. In 1720, he first displayed his comic powers in the character of Falstaff, and soon after appeared to as great advantage in Sir John Brute; but it was upon Booth's quitting the stage that Quin appeared to full advantage, in the part of Cato. He continued a favourite performer until the year 1748, when, on some disgust between him and Mr Rich the manager, he retired to Bath, and only came up annually to act for the benefit of his friend Ryan; until the loss of two front teeth spoiled his utterance for the stage. While Mr Quin continued upon the stage, he constantly kept company with the greatest geniuses of the age. He was well known to Pope and Swift; and the earl of Chesterfield frequently invited him to his table; but there was none for whom he entertained a higher esteem than for the ingenious Mr Thomson, to whom he made himself known by an act of generosity that does the greatest honour to his character; and for an account of which see our life of THOMSON. Mr Quin's judgment in the English language recommended him to his royal highness Frederick prince of Wales, who appointed him to instruct his children in speaking and reading with a graceful propriety; and Quin being informed of the elegant manner in which his present majesty delivered his first gracious speech from the throne, he cried out in a kind of ecstasy, "Ay—I taught the boy to speak!" Nor did his majesty forget his old tutor; for, soon after his accession to the throne, he gave orders, without any application being made to him, that a genteel pension should be paid to Mr Quin during his life. Mr Quin, indeed, was not in absolute need of this royal benefaction; for as he was never married, and had none but distant relations, he sunk 2000 l. which was half his fortune, in an annuity, for which he obtained 200 l. a-year; and with about 2000 l. more in the funds, lived in a decent manner during the latter part of his life at Bath, from whence he carried on a regular correspondence with Mr Garrick, and generally paid a visit to his friends in the metropolis once a-year, when he constantly passed a week or two at Mr Garrick's villa at Hampton. He died of a fever in 1766.

QUINARIUS, was a small Roman coin equal to half the denarius, and consequently worth about three pence three farthings sterling. See MONEY.

Quin,
Quillens.

Quinque-
remis.

It was called *quinarius*, because it contained the value of five asses, in the same manner as the denarius was named from its containing ten.

QUINAUT (Philip), a celebrated French poet, born of a good family at Paris in 1635. He cultivated poetry from his infancy, and 16 dramatic pieces of his were acted between the year 1653 and 1666. In the mean time, Quinaut was not so much devoted to poetry but that he applied himself to the study of the law; and made his fortune by marrying the widow of a rich merchant to whom he had been useful in his profession. Quinaut afterwards turned his attention to the composing of operas, which were set to music by the famous Lully; and Lully was charmed with a poet whose verses were not too nervous to yield to the capricious airs of music. He died in 1683, after having enjoyed a handsome pension from Louis XIV. for many years: and we are told he was extremely penitent in his last illness for all those of his compositions which tended to inspire love and pleasure.

QUINCE, in botany. See **CYDONIA**.

QUINCUNX, in Roman antiquity, denotes any thing that consists of five-twelfths of another; but particularly of the *as*.

QUINCUNX Order, in gardening, is a plantation of trees, disposed originally in a square consisting of five trees, one at each corner, and a fifth in the middle; which disposition, repeated again and again, forms a regular grove, wood, or wilderness.

QUINDECAGON, in geometry, a plain figure with 15 sides and 15 angles.

QUINDECENVIRI, in Roman antiquity, a college of 15 magistrates, whose business it was to preside over the sacrifices. They were also the interpreters of the Sybil's books; which, however, they never consulted but by an express order of the senate.

QUINQUAGENARIUS, in Roman antiquity, an officer who had the command of 50 men.

QUINQUAGESIMA SUNDAY, Shrove Sunday, so called as being about the 50th day before Easter.

QUINQUATRIA, or **QUINQUATRUS**, was a festival kept at Rome in honour of Minerva, which began on the 18th of March, or as others will have it on the 19th, and lasted five days. On the first day they offered sacrifices and oblations without the effusion of blood; the second, third, and fourth, were spent in shows of gladiators; and on the fifth day they went in procession through the city. Scholars had a vacation during the solemnity, and presented their masters at this time with a gift or fee, called *Minerval*. Boys and girls used now to pray to the goddess Minerva for wisdom and learning, of which she had the patronage. Plays were acted, and disputations held, at this feast, on subjects of polite literature. The quinquatria were so called, because they lasted for five days. There seems to be a strong resemblance betwixt this festival and the panathenæa of the Greeks.

QUINQUENNALIS, in Roman antiquity, a magistrate in the colonies and municipal cities of that empire, who had much the same office as the ædile at Rome.

QUINQUEREMIS, in the naval architecture of the ancients, a name given to a galley which had five rows of oars. They divided their vessels in general into *monocrota* and *polycrota**. The former had only one tire

of rowers: the latter had several tires of them, from two or three up to 20, 30, or even 40; for such a vessel we have an account of in the time of Philopater, which required no less than 4000 men to row it.

Meibom has taken off from the imaginary improbability of there ever having been such a vessel, by reducing the enormous height supposed necessary for such a number of rows of oars and men to work them, by finding a better way of placing the men than others had thought of. The quinqueres of the ancients had 420 men in each; 300 of which were rowers, and the rest soldiers. The Roman fleet at Messina consisted of 330 of these ships; and the Carthaginian, at Lilybæum, of 350 of the same size. Each vessel was 150 feet long. Thus 130,000 men were contained in the one, and 150,000 in the other, with the apparatus and provisions necessary for such expeditions as they were intended for. This gives so grand an idea of the ancient naval armaments, that some have questioned the truth of the history: but we find it related by Polybius, an historian too authentic to be questioned, and who expresses his wonder at it while he relates it.

QUINQUEVIRI, in Roman antiquity, an order of five priests, peculiarly appointed for the sacrifices to the dead, or celebrating the rites of Erebus.

QUIQUINA. See **CINCHONA**.

QUINZY, or **QUINZY**. See **MEDICINE**, n° 177—183.

QUINTEN, a town of France, in Bretagne, with the title of a duchy, and a handsome castle. It is seated in a valley near the river Guy, and near a large forest of the same name, eight miles south of St Brieux, and 200 west of Paris. W. Long. 2. 40. N. Lat. 48. 26.

QUINTESSENCE, in chemistry, a preparation consisting of the essential oil of some vegetable substance, mixed and incorporated with spirit of wine.

QUINTESSENCE, in alchemy, is a mysterious term, signifying the fifth or last and highest essence of power in a natural body.

QUINTILE, in astronomy, an aspect of the planets when they are 72 degrees distant from one another, or a fifth part of the zodiac.

QUINTILIANUS (Marcus Fabius), a celebrated Latin orator, and the most judicious critic of his time, was a native of Calagurris, or Calahorra, in Spain; and was the disciple of Domitius Afer, who died in the year 59. He taught rhetoric at Rome for 20 years with great applause: and not only laid down rules for speaking, but exhibited his eloquence at the bar. Some authors imagine, but with little foundation, that he arrived to the consulship; but it is more certain that he was preceptor to the grandsons of the emperor Domitian's sister. There is still extant his excellent work, intitled, *Institutiones Oratoria*, which is a treatise of rhetoric in 12 books; where his precepts, judgment, and taste, are justly admired. These institutions were found entire by Poggius, in an old tower of the abbey of St Gal, and not in a grocer's shop in Germany as some authors have imagined. There is also attributed to Quintilian a dialogue *De causis corruptæ eloquentiæ*; but it is more commonly ascribed to Tacitus. The best editions of Quintilian's works are those of Mr Obrecht, published at Strasburg in 2 vols 4to, in 1698, and of M. Capperonier, in folio. There is an English translation by Mr Guthrie.

nus.

* See **Poly-
crota**.

Quintilians
||
Quintus.

Quintilian had a son of the same name, on whom he bestows great praises. This son ought not to be confounded with Quintilian the father, or rather the grandfather, of him who is the subject of this article, and who wrote 145 declamations. Ugolin of Parma published the first 136 in the 15th century; the nine others were published in 1563 by Peter Ayrault, and afterwards by Peter Pithou in 1580. There have also been 19 other declamations printed under the name of Quintilian the Orator; but, in the opinion of Vossius, they were written neither by that orator nor his grandfather.

QUINTILIANS, a sect of ancient heretics, thus called from their prophets Quintilia. In this sect the women were admitted to perform the sacerdotal and episcopal functions. They attributed extraordinary gifts to Eve for having first eaten of the tree of knowledge; told great things of Mary the sister of Moses, as having been a prophetess, &c. They added, that Philip the deacon had four daughters, who were all prophetesses, and were of their sect. In these assemblies it was usual to see the virgins entering in white robes, personating prophetesses.

QUINTIN MATSYS, also called the *Farrier of Antwerp*, famous for being transformed, by the force of love, from a blacksmith to a painter. He had followed the trade of a blacksmith and farrier near twenty years; when falling in love with a painter's daughter who was very handsome, and disliked nothing but his trade, he quitted it, and betook himself to painting, in which he made a very uncommon progress. He was a diligent and careful imitator of ordinary life, and succeeded better in representing the defects than the beauties of nature. Some historical performances of this master deserve commendation, particularly a Descent from the Cross, in the Cathedral at Antwerp: but his best known picture is that of the two Misers in the gallery at Windsor. He died in 1529.

QUINTINIE (John de la), a celebrated French gardener, born at Poitiers in 1626. He was brought up to the law; and acquitted himself so well at the bar as to acquire the esteem of the chief magistrate. M. Tamboneau, president of the chamber of accounts, engaged him to undertake the preceptorship of his only son, which Quintinie executed entirely to his satisfaction; applying his leisure hours to the study of writers on agriculture, ancient and modern, to which he had a strong inclination. He gained new lights by attending his pupil to Italy; for all the gardens about Rome being open to him, he failed not to add practice to his theory. On his return to Paris, M. Tamboneau gave up the management of his garden entirely to him; and Quintinie applied so closely to it, that he became famous all over France. Louis XIV. erected a new office purposely for him, that of director of the royal fruit and kitchen gardens; and these gardens, while he lived, were the admiration of the curious. He lived to a good old age, though we learn not the time of his death; his Directions for the Management of Fruit and Kitchen Gardens are esteemed all over Europe.

QUINTUS CALABER, a Greek poet, who wrote a large Supplement to Homer's Iliad, in 14 books, in which a relation is given of the Trojan war from the death of Hector to the destruction of Troy. It is conjectured, from his style and manner, that he lived in the fifth century. Nothing certain can be collected either

concerning his person or country. His poem was first made known by Cardinal Bessarion, who discovered it in St Nicolas's church, near Otranto in Calabria; from whence the author was named *Quintus Calaber*. It was first published at Venice by Aldus, but it is not said in what year.

QUINTUS CURTIUS. See CURTIUS.

QUINZY, QUINSEY, or *Angina Pectoris*. See MEDICINE, n° 403.

QUIRE OF PAPER, the quantity of 24 or 25 sheets.

QUIRINALIA, in antiquity, a feast celebrated among the Romans in honour of Romulus.

QUIRITES, in Roman antiquity. In consequence of the agreement entered into by Romulus and Tatius king of the Sabines, Rome was to retain its name, taken from Romulus; and the people were to be called *Quirites*, from Cures, the principal town of the Sabines, a name used in all public addresses to the Roman people. —Dion. Hal. says, that each particular citizen was to be called *Romanus*, and the collective body of them *Quirites*; yet it appears by this ancient form of words used at funerals, *Ollus Quiris letho datus est*, that each private citizen was also called *Quiris*.

The origin of the word *Quirites*, which was at first peculiar to the Sabines, and became, in Romulus's time, the general name of the inhabitants of Rome, has been much sought for; and the most probable account antiquity gives us of it, is this: The word *Quiris*, according to Plutarch and some others, signified, in the Sabine language, both "a dart," and "a warlike deity armed with a dart." It is uncertain whether the god gave name to the dart, or the dart to the god. But be that as it will, this *Quiris*, or *Quirinus*, was either Mars or some other god of war; and the worship of *Quiris* continued in Rome all Romulus's reign: but after his death he was honoured with the name *Quirinus*, and took the place of the god *Quiris*.

QUIRK, in a general sense, denotes a subtilty or artful distinction.

QUIRK, in building, a piece of ground taken out of any regular ground-plot, or floor: thus, if the ground-plot were oblong or square, a piece taken out of a corner to make a court or yard, &c. is called a *quirk*.

QUISQUALIS, in botany: A genus of the monogynia order, belonging to the decandria class of plants; and in the natural method ranking under the 31st order, *Veprecule*. The calyx is quinquefid and filiform; the petals five; the fruit is a quinqueangular plum. There is only one species, viz. INDICA.

QUITO, a town of South America, in Peru (see PERU, p. 213.), seated between two chains of high mountains called *Cordillera de los Andes*, on much higher ground than the rest of habitable Peru. It is 300 yards higher than the level of the sea according to the exactest observations. The town is 1600 yards long and 1200 broad, and is the seat of a bishop. It contains about 35,000 inhabitants, one third of whom are originally Spaniards. Among the inhabitants are some persons of high rank and distinction, descended either from the original conquerors, or persons who at different times came from Spain invested with some lucrative post. The number of these, however, is but small. The commonalty, besides Spaniards, consist of Mestizos, Indians, and Negroes; but the last are not proportionally

Quintus
||
Quito.

Quito
||
Quoin.

proportionally numerous. Merchandizes and commodities of all sorts are extremely dear, partly on account of the difficulty of bringing them.

There are several religious communities at Quito, and two colleges or universities governed by Jesuits and Dominicans.

The principal courts held at Quito are that of the royal audience, which consists of a president, who is governor of the province with regard to law affairs; four auditors, who are at the same time civil and criminal judges; a royal fiscal, who, besides the causes brought before the audience, takes cognizance of every thing relating to the revenue; and an officer styled the *protector of the Indians*, who solicits for them, and when they are injured pleads in their defence. The next is the treasury, the chief officers of which are an accountant, a treasurer, and a royal fiscal. The tribunal of the Croisade, which has a commissary, who is generally some dignitary of the church, and a treasurer. There is also a treasury for the effects of persons deceased: an institution established all over the Indies, for receiving the goods of those whose lawful heirs are in Spain, in order to secure them from those accidents to which they might be liable in private hands. There is likewise a commissary of the inquisition, with an alguazil-major and familiars, appointed by the inquisition at Lima. The corporation consists of a corregidor, two ordinary alcaldes, chosen annually, and regidores. The latter superintend the election of the alcaldes, which is attended with no small disturbance, the people being divided into two parties, the Creoles and Europeans.

QUITTER-BONE, in farriery. See there, § xl. 4.

QUIT-RENT (*quietus redditus*, i. e. "quiet rent,") is a certain small rent payable by the tenants of manors, in token of subjection, and by which the tenant goes quiet and free. In ancient records it is called *white rent*, because paid in silver money, to distinguish it from rent-corn, &c.

QUOIN, or COIN, on board a ship, a wedge fa-

stened on the deck close to the breach of the carriage of a gun, to keep it firm up to the ship's side. Cantic quoins are short three-legged quoins put between casks to keep them steady.

Quoins
||
Quotient.

QUOINS, in architecture, denote the corners of brick or stone walls. The word is particularly used for the stones in the corners of brick buildings. When these stand out beyond the brick-work, their edges being chamfred off, they are called *rustic quoins*.

QUOTIDIAN, any thing which happens every day. Hence, when the paroxysms of an ague recur every day, it is called a *quotidian ague*. See MEDICINE, n° 161—164.

QUOTIDIANA DECEPTIVA. See MEDICINE, n° 150.

QUOAD HOC, is a term used in the pleadings and arguments of lawyers; being as much as to say, As to this thing the law is so and so.

QUORUM, a word frequently mentioned in the statutes, and in commissions both of justices of the peace and others. It is thus called from the words of the commission, *quorum A. B. unum esse volumus*. For an example, where a commission is directed to seven persons, or to any three of them, whereof A. B. and C. D. are to be two; in this case, they are said to be of the quorum, because the rest cannot proceed without them: so a justice of the peace and quorum is one without whom the rest of the justices in some cases cannot proceed.

QUOTIENT, in arithmetic, the number resulting from the division of a greater number by a smaller; and which shows how often the smaller is contained in the greater, or how often the divisor is contained in the divided. The word is formed from the Latin *quoties*; *q. d.* How often is such a number contained in such another?

In division, as the divisor is to the dividend, so is unity to the quotient.—Thus the quotient of 12 divided by 3 is 4; which is thus disposed, 3) 12 (4 quotient. See ARITHMETIC.

R.

R, or *r*, a liquid consonant, being the 17th letter of our alphabet. Its sound is formed by a guttural extrusion of the breath vibrated through the mouth, with a sort of quivering motion of the tongue drawn from the teeth, and canulated with the tip a little elevated towards the palate. In Greek words it is frequently aspirated with an *h* after it, as in *rhapsody*, *rhetoric*, &c. otherwise it is always followed by a vowel at the beginning of words and syllables.

In the notes of the ancients, R. or RO. signifies *Roma*; R. C. *Romana civitas*; R. G. C. *rei gerende causa*; R. F. E. D. *recte factum et dictum*; R. G. F. *regis filius*; R. P. *res publica*, or *Romani principes*; and R. R. R. F. F. F. *res Romana ruet ferro, fame, flamma*.

Used as a numeral, R. anciently stood for 80; and with a dash over it, thus \overline{R} , for 80,000; but the Greek ρ , ρ , with a small mark over it, signified 100; with the same mark under it, it denoted 1000×100 ; thus ρ signified 100,000. In the Hebrew numeration \aleph denoted 200: and with two horizontal points over it \aleph \times 200; thus \aleph = 200,000.

In the prescriptions of physicians, R or \mathcal{R} stands for *recipe*, i. e. "take."

RAAB, a town of Lower Hungary, capital of Javerin, with a castle and a bishop's see. It is a strong frontier bulwark against the Turks, and has two bridges, one over a double ditch, and another that leads towards Alba Regalis. The surrounding country is plain, and there

Rabac
||
Rabetting.

there is nothing that seems to command it but a small hill at some distance, which is undermined and may be blown up. It was taken by Amurath III. with the loss of 20,000 men; but was surprised soon after by Count Palfi, who killed all the Turks that were found therein. It is seated at the confluence of the rivers Rab and Rabinitz, not far from the Danube, 32 miles west of Gran, and 55 south-east of Vienna. E. Long. 17. 25. N. Lat. 47. 48.

RABAC, a small port on the Arabian coast of the Red Sea, in N. Lat. 22° 35' 40" by Mr Bruce's account. The entry to the harbour is from the E. N. E. and is about a quarter of a mile broad. The port extends about two miles in length to the eastward. The mountains are about three leagues to the north, and the town about four miles north by east from the entrance to the harbour. The water is good, and all ships may be supplied here from the wells which are in the neighbourhood of the town. The country is bare and uncultivated; but from the appearance of it, and the freshness of the water, Mr Bruce supposes that it sometimes rains among the mountains here, which is the more probable as it is considerably within the tropic.

RABAT, a large and handsome sea-port town of Africa, in the kingdom of Fez and province of Tremesen. It has fine mosques and handsome palaces, and is seated at the mouth of the river Burrigrig, almost in the mid-way between Fez and Tangier. W. Long. 5. 28. N. Lat. 34. 40.

Rabat, together with Sallee, which is opposite to it, was formerly famous for fitting out piratical vessels; but the late emperor Sidi Mahomet subdued them both, and annexed them to the empire; since which time the harbour of Rabat has been so filled with the sand washed in by the sea as to render it unfit to carry on such piracies in future.

The town of Rabat, whose walls inclose a large space of ground, is defended on the sea-side by three forts tolerably well finished, which were erected some little time ago by an English renegado, and furnished with guns from Gibraltar. The houses in general are good, and many of the inhabitants are wealthy. The Jews, who are very numerous in this place, are generally in better circumstances than those of Larache or Tangier, and their women are extremely beautiful.

The castle, which is very extensive, contains a strong building, formerly used by the late emperor as his principal treasury, and a noble terrace, which commands an extensive prospect of the town of Sallee, the ocean, and all the neighbouring country. There are also the ruins of another castle, which is said to have been built by Jacob Almonzor, one of their former emperors, and of which at present very little remains but its walls, containing within them some very strong magazines for powder and naval stores. On the outside of these walls is a very high and square tower, handsomely built of cut stone, and called the tower of *Haffen*. From the workmanship of this tower, contrasted with the other buildings, a very accurate idea may be formed how greatly the Moors have degenerated from their former splendour and taste for architecture.

RABBETTING, in carpentry, the planning or cutting of channels or grooves in boards, &c.

In ship-carpentry, it signifies the letting in of the planks of the ship into the keel; which, in the rake and

run of a ship, is hollowed away, that the planks may join the closer.

RABBI, or RABBINS, a title which the Pharisees and doctors of the law among the Jews assumed, and literally signifies *masters* or *excellents*.

There were several gradations before they arrived at the dignity of a rabbin; which was not conferred till they had acquired the profoundest knowledge of the law and the traditions. It does not, however, appear that there was any fixed age or previous examination necessary; but when a man had distinguished himself by his skill in the written and oral law, and passed through the subordinate degrees, he was saluted a rabbin by the public voice.

Among the modern Jews, for near 700 years past, the learned men retain no other title than that of *rabbi*, or *rabbins*; they have great respect paid them, have the first places or seats in their synagogues, determine all matters of controversy, and frequently pronounce upon civil affairs; they have even power to excommunicate the disobedient.

RABBINISTS, among the modern Jews, an appellation given to the doctrine of the rabbins concerning traditions, in opposition to the Caraites; who reject all traditions. See CARAITE.

RABELAIS (Francis), a French writer famous for his facetiousness, was born at Chinon in Touraine about the year 1483. He was first a Franciscan friar; but quitting his religious habit studied physic at Montpellier, where he took his doctor's degree. It is said, that the chancellor du Pratt having abolished the privileges of the faculty of physic at Montpellier by a decree of the parliament, Rabelais had the address to make him revoke what he had done; and that those who were made doctors of that university wore Rabelais's robe, which is there held in great veneration. Some time after, he came to Rome, in quality of physician in ordinary to Cardinal John du Bellay archbishop of Paris. Rabelais is said to have used the freedom to jeer Pope Paul III. to his face. He had quitted his religious connections for the sake of leading a life more agreeable to his taste; but renewed them on a second journey to Rome, when he obtained, in 1536, a brief to qualify him for holding ecclesiastical benefices; and, by the interest of his friend Cardinal John du Bellay, he was received as a secular canon in the abbey of St Maur near Paris. His profound knowledge in physic rendered him doubly useful; he being as ready, and at least as well qualified, to prescribe for the body as for the soul: but as he was a man of wit and humour, many ridiculous things are laid to his charge, of which he was quite innocent. He published several things; but his chief performance is a strange incoherent romance, called the *History of Gargantua and Pantagruel*, being a satire upon priests, popes, fools, and knaves of all kinds. This work contains a wild, irregular profusion of wit, learning, obscenity, low conceits, and arrant nonsense; hence the shrewdness of his satire, in some places where he is to be understood, gains him credit for those where no meaning is discoverable. Some allusions may undoubtedly have been so temporary and local as to be now quite lost: but it is too much to conclude thus in favour of every unintelligible rhapsody; for we were not without English writers of great talents, whose sportive genuineness have betrayed them into puerilities, no less incoherent as

Rabbi
||
Rabelais.

Rabbit.

the times of writing than those of Rabelais appear above two centuries after. He died about 1553.

RABBIT, in zoology. See *LEPUS*.

The buck rabbits, like our bear cats, will kill the young ones if they can get at them; and the does in the warrens prevent this, by covering their stocks, or nests, with gravel or earth, which they close so artificially up with the hinder part of their bodies, that it is hard to find them out. They never suckle their young ones at any other time than early in the morning and late at night; and always, for eight or ten days, close up the hole at the mouth of the nest, in this careful manner when they go out. After this they begin to leave a small opening, which they increase by degrees; till at length, when they are about three weeks old, the mouth of the hole is left wholly open that they may go out; for they are at that time grown big enough to take care of themselves, and to feed on grass.

People who keep rabbits tame for profit, breed them in hutches; but these must be kept very neat and clean, else they will be always subject to diseases. Care must be taken also to keep the bucks and does apart till the latter have just kindled; then they are to be turned to the bucks again, and to remain with them till they shun and run from them.

The general direction for the choosing of tame rabbits is, to pick the largest and fairest; but the breeder should remember that the skins of the silver-haired ones sell better than any other. The food of the tame rabbits may be colewort and cabbage-leaves, carrots, parsneps, apple-rinds, green corn, and vetches, in the time of the year; also vine-leaves, grass, fruits, oats, and oatmeal, milk-thistles, sow-thistles, and the like: but with these moist foods they must always have a proportionable quantity of the dry foods, as hay, bread, oats, bran, and the like, otherwise they will grow potbellied, and die. Bran and grains mixed together have been also found to be very good food. In winter they will eat hay, oats, and chaff, and these may be given them three times a-day; but when they eat green things, it must be observed that they are not to drink at all, for it would throw them into a dropsy. At all other times a very little drink serves their turn, but that must always be fresh. When any green herbs or grass are cut for their food, care must be taken that there be no hemlock among it; for though they will eat this greedily among other things when offered to them, yet it is sudden poison to them.

Rabbits are subject to two principal infirmities. First, the rot, which is caused by giving them too large a quantity of greens, or from giving them fresh gathered with the dew or rain hanging in drops upon them. It is over-moisture that always causes this disease. The greens therefore are always to be given dry; and a sufficient quantity of hay, or other dry food, intermixed with them, to take up the abundant moisture of their juices. On this account the very best food that can be given them, is the shortest and sweetest hay that can be got, of which one load will serve 200 couples a year; and out of this stock of 200, 200 may be eat in the family, 200 sold to the markets, and a sufficient number kept in case of accidents.

The other general disease of these creatures is a sort of madness: this may be known by their wallowing and tumbling about with their heels upwards, and hop-

ping in an odd manner into their boxes. This distemper is supposed to be owing to the rankness of their feeding; and the general cure is the keeping them low, and giving them the prickly herb called *tare-thistle* to eat.

The general computation of males and females is, that one buck-rabbit will serve for nine does: some allow 10 to one buck; but those who go beyond this always suffer for it in their breed.

The wild rabbits are either to be taken by small cur-dogs, or by spaniels bred up to the sport; and the places of hunting those who straggle from their burrows, is under close hedges or bushes, or among corn-fields and fresh pastures. The owners use to course them with small grey-hounds; and though they are seldom killed this way, yet they are driven back to their burrows, and are prevented from being a prey to others. The common method is by nets called *purse nets*, and ferrets. The ferret is sent into the hole to fetch them out; and the purse-net being spread over the hole, takes them as they come out. The ferrets' mouths must be muffled, and then the rabbit gets no harm. For the more certain taking of them, it may not be improper to pitch up a hay-net or two, at a small distance from the burrows that are intended to be hunted: thus very few of the number that are attempted will escape.

Some who have not ferrets smoke the rabbits out of their holes with burning brimstone and orpiment. This certainly brings them out into the nets: but then it is a very troublesome and offensive method; and is very detrimental to the place, as no rabbit will for a long time afterwards come near the burrows which have been fumed with those stinking ingredients.

The testicle of a rabbit is a very good object for examining the structure of this part of generation in animals. The whole substance of the testicle in this animal is made up of vessels, which lie round folds in the manner of the smaller intestines: but then both ends of each roll meet at their insertion, which seems to be made into the *ductus nervosus*; and every one of these little rolls is curiously embroidered with other vessels, which, from their red colour, appear to be arteries and veins. The several little rolls lie in ranges, disposed with an uniformity which is very agreeable to the eye. Every one of these rolls is not a single and entire tube, but each consists of several tubes, beside the veins and arteries which embroider it. This is best distinguished by the cutting one of the rolls transversely, and then examining the cut end with a glass, which will appear to be made up of the cut and open ends of four, five, or more parallel tubes, which together form the roll, or single tube, as it appears to the eye, being all wrapped up in one common and very thin membrane. These are so tender that they cannot be explicated and viewed distinct, as De Graaf tells us those of the testicles of a rat and of some other animals may. These, however, as well as the others, are only made up of a congeries of vessels, and the liquors, which are their contents, without any intermediate substance, or any thing of that parenchyma which many authors have talked of. The testicles of a bull have the greatest appearance of a fleshy texture of those of any known animal; yet even these afford no particle of parenchyma, or flesh, when examined by glasses in any sort of preparation, whether boiled, raw, soaked in spirits, or in whatever other state.

The

Rabbit.

Rabirius
||
Racine.

The testicles of various animals are very variously composed, but all in this general manner of vessels variously rolled and folded together : and even the human testicles are of the same sort ; being composed solely of rolls of vessels, without any intermediate substance, be it called by whatever name, but only consisting of vessels and their liquors.

RABIRIUS (C.) a Roman knight, who lent an immense sum of money to Ptolemy Auletes king of Egypt. The monarch afterwards not only refused to repay him, but even confined him, and endangered his life. Rabirius escaped from Egypt with difficulty ; but at his return to Rome he was accused by the senate of having lent money to an African prince for unlawful purposes. He was ably defended by Cicero, and acquitted with difficulty.—There was a Latin poet of the same name in the age of Augustus. He wrote a poem on the victory which the emperor had gained over Antony at Actium. Seneca has compared him to Virgil for elegance and majesty ; but Quintilian is not so favourable to his poetry.—And there was an architect in the reign of Domitian, called *Rabirius*. He built a celebrated palace for the emperor, of which the ruins are still seen at Rome.

RACCOON. See *URSUS*.

RACE, in general, signifies running with others in order to obtain a prize, either on foot, or by riding on horseback, in chariots, &c.

The race was one of the exercises among the ancient Grecian games, which was performed in a course containing 125 paces ; and those who contended in these foot-races were frequently clothed in armour. Chariot and horse races also made a part of these ancient games.

Races were known in England in very early times. Fitz-Stephen, who wrote in the days of Henry II. mentions the great delight that the citizens of London took in the diversion. But by his words, it appears not to have been designed for the purposes of gaming, but merely to have sprung from a generous emulation of showing a superior skill in horsemanship.

Races appear to have been in vogue in the reign of Queen Elizabeth, and to have been carried to such excess as to injure the fortunes of the nobility. The famous George earl of Cumberland is recorded to have wasted more of his estate than any of his ancestors ; and chiefly by his extreme love to horse-races, tiltings, and other expensive diversions. It is probable that the parsimonious queen did not approve of it ; for races are not among the diversions exhibited at Kennelworth by her favourite Leicester. In the following reign, were places allotted for the sport : Croydon in the south, and Garterly in Yorkshire, were celebrated courses. Camden also says, that in 1607 there were races near York, and the prize was a little golden bell. See *RACING*.

RACE, in genealogy, a lineage or extraction continued from father to son. See *DESCENT*.

RACINE (John), of the French academy, treasurer of France in the generality of Moulins, and secretary to his majesty, was born at Ferre-Milon in 1639. He had a fine genius for the *Belles Lettres*, and became one of the first poets of the age. He produced his *Thebaïde* when but very young ; and afterwards other pieces, which met with great success, though they appeared when Corneille was in his highest repu-

tation. In his career, however, he did not fail to meet with all that opposition which envy and cabal are ever ready to set up against a superior genius. It was partly owing to a chagrin from this circumstance that he took a resolution to quit the theatre forever ; although his genius was still in full vigour, being not more than 38 years of age. But he had also imbibed in his infancy a deep sense of religion ; and this, though it had been smothered for a while by his connections with the theatre, and particularly with the famous actress Champ-melle, whom he greatly loved, and by whom he had a son, now at length broke out, and bore down all before it. In the first place, he resolved not only to write no more plays, but to do a rigorous penance for those he had written ; and he actually formed a design of becoming a Carthusian friar. His religious director, however, a good deal wiser than he, advised him to think more moderately, and to take measures more suitable to his character. He put him upon marrying, and settling in the world : with which proposal this humble and tractable penitent complied ; and immediately took to wife the daughter of a treasurer of France for Amiens, by whom he had seven children.

He had been admitted a member of the French academy in 1673, in the room of La Mothe le Vayer deceased ; but spoiled the speech he had made upon that occasion by pronouncing it with too much timidity. In 1677, he was nominated with Boileau, with whom he was ever in strict friendship, to write the history of Louis XIV. ; and the public expected great things from two writers of their distinction, but were disappointed. Boileau and Racine, after having for some time laboured at this work, perceived that it was entirely opposite to their genius.

He spent the latter years of his life in composing a history of the house of Port-Royal, the place of his education ; which, however, though finely drawn up, as many have asserted, has not been published. Too great sensibility, say his friends, but more properly an impotence of spirit, shortened the days of this poet.—Though he had conversed much with the court, he had not learned the wisdom, which is usually learned there, of disguising his real sentiments. Having drawn up a well-reasoned and well-written memorial upon the miseries of the people, and the means of relieving them, he one day lent it to Madam de Maintenon to read ; when the king coming in, and demanding what and whose it was, commended the zeal of Racine, but disapproved of his meddling with things that did not concern him : and said with an angry tone, “ Because he knows how to make good verses, does he think he knows every thing ? And would he be a minister of state, because he is a great poet ? ” These words hurt Racine greatly : he conceived dreadful ideas of the king’s displeasure ; and his chagrin and fears brought on a fever, of which he died the 22d of April 1699.

The king, who was sensible of his great merit, and always loved him, sent often to him in his illness ; and finding after his death that he had more glory than riches, settled a handsome pension upon his family.—There is nothing in the French language written with more wit and elegance than his pieces in prose. Besides his plays, several of his letters have been published ; he also wrote spiritual songs, epigrams, &c. Racine’s

works

Racing.

works were printed at Amsterdam in 1722, in 2 vols. 12mo, and the next year a pompous edition was printed in 2 vols. quarto.

RACING, the riding heats for a plate, or other premium. See PLATE. The amusement of horseracing, which is now so common, was not unknown among the great nations of antiquity, nor wholly unpractised by our ancestors in Britain, as we have already mentioned in the article RACE. In 1599, private matches between gentlemen, who were their own jockies and riders, were very common; and, in the reign of James I. public races were established at various places, when the discipline, and mode of preparing the horses for running, &c. were much the same as they are now. The most celebrated races of that time were called bell-courses, the prize of the conqueror being a bell: hence, perhaps, the phrase of *bearing the bell*, when applied to excellence, is derived. In the latter end of Charles I.'s reign, races were performed in Hyde-Park. Newmarket was also a place for the same purpose, though it was first used for hunting. Racing was revived soon after the Restoration, and much encouraged by Charles II. who appointed races for his own amusement at Datchet Mead, when he resided at Windsor. Newmarket, however, now became the principal place. The king attended in person, established a house for his own accommodation, and kept and entered horses in his own name. Instead of bells, he gave a silver bowl or cup value 100 guineas; on which prize the exploits and pedigree of the successful horse were generally engraved. Instead of the cup or bowl, the royal gift is now a hundred guineas. William III. not only added to the plates, but even founded an academy for riding; and Queen Anne continued the bounty of her ancestors, adding several plates herself. George I. towards the end of his reign, discontinued the plates, and gave in their room a hundred guineas. An act was passed in the 13th year of the reign of George II. for suppressing races by ponies and other small and weak horses, &c. by which all matches for any prize under the value of 50l. are prohibited, under a penalty of 200l. to be paid by the owner of each horse running, and 100l. by such as advertised the plate; and by which each horse entered to run, if five years old, is obliged to carry ten stones; if six, eleven; and if seven, twelve. It is also ordained, that no person shall run any horse at a course, unless it be his own, nor enter more than one horse for the same plate, upon pain of forfeiting the horses; and also every horse-race must be begun and ended in the same day. Horses may run for the value of 50l. with any weight, and at any place. 13 Geo. II. cap. 19. 18 Geo. II. cap. 34. Pennant's British Zoology, vol. i. p. 6, &c. Berenger's History and Art of Horsemanship, vol. i. p. 185, &c. At Newmarket there are two courses, the long and the round: the first is exactly four miles and about 380 yards, *i. e.* 7420 yards. The second is 6640 yards. Childers, the swiftest horse ever known, has run the first course in seven minutes and a half, and the second in six minutes forty seconds; which is at the rate of more than forty-nine feet in a second. But all other horses take up at least seven minutes and fifty seconds in completing the first and longest course, and seven minutes only in the shortest, which is at the rate of more than forty-seven feet in a second. And it is commonly supposed

that these courses cover, at every bound, a space of ground in length about twenty-four English feet. Race-horses have been for some time an object of taxation.

RACHITIS, the RICKETS. See MEDICINE, n° 347.

RACK (Edmund), a person well known in the literary world by his attachment to, and promotion of, agricultural knowledge: he was a native of Norfolk (England), a Quaker. His education was common, and he was apprenticed originally to a shopkeeper: his society was select in this situation, and by improving himself in learning, his conversation was enjoyed by a respectable acquaintance. He wrote many essays, poems, and letters, and some few controversial tracts. At length he settled, about his 40th year, at Bath in 1775, and was soon introduced to the most eminent literati of that place, among whom Dr Wilson and Mrs Macaulay highly esteemed him for his integrity and abilities. In 1777 he published *Mentor's Letters*, a moral work, which has run through many editions. But this year he gained great celebrity by his plan of an agricultural society, which was soon adopted by four counties. He still further advanced his fame by his papers in the Farmer's Magazine, and his communications in the Bath Society's papers; a work remarkable for its ingenuity and spirit. His last engagement was in the History of Somersetshire, where the topographical parochial surveys were his. This work, in 3 vols 4to, was published in 1791, by his colleague the Reverend Mr Collinson. —Mr Rack died of an asthma in February 1787, aged 52.

RACK, an engine of torture, furnished with pulleys, cords, &c. for extorting confession from criminals.—The trial by rack is utterly unknown to the law of England; though once, when the dukes of Exeter and Suffolk, and other ministers of Henry VI. had laid a design to introduce the civil law into Britain as the rule of government; for a beginning thereof they erected a rack for torture, which was called in derision the duke of Exeter's daughter, and still remains in the Tower of London, where it was occasionally used as an engine of state, not of law, more than once in the reign of Queen Elizabeth. But when, upon the assassination of Villiers duke of Buckingham, by Felton, it was proposed in the privy council to put the assassin to the rack, in order to discover his accomplices; the judges, being consulted, declared unanimously, to their own honour and the honour of the English law, that no such proceeding was allowable by the laws of England. It seems astonishing that this usage of administering the torture should be said to arise from a tenderness to the lives of men; and yet this is the reason given for its introduction in the civil law, and its subsequent adoption by the French and other foreign nations, viz. because the laws cannot endure that any man should die upon the evidence of a false, or even a single witness, and therefore contrived this method that innocence should manifest itself by a stout denial, or guilt by a plain confession: thus rating a man's virtue by the hardness of his constitution, and his guilt by the sensibility of his nerves. The Marquis Beccaria, in an exquisite piece of railery, has proposed this problem, with a gravity and precision that are truly mathematical: "The force of the muscles and the sensibility of the nerves of an innocent person being given; it is required to find the degree of pain necessary to make him confess

Rachitis,
Rack

Rack
||
Radcliffe.

confess himself guilty of a given crime." See *Act of Faith*, *INQUISITION*, and *TORTURE*.

RACK, a spirituous liquor made by the Tartars of *Tongusta*. This kind of rack is made of mare's milk, which is left to be sour, and afterwards distilled twice or thrice between two earthen pots closely stopped; whence the liquor runs through a small wooden pipe. This liquor is more intoxicating than brandy distilled from wine.

RACK, or *Arack*. See *ARACK*.

To Rack Wines, &c. To draw them off from their lees, after having stood long enough to ebb and settle. Hence rack-vintage is frequently used for the second voyage the wine-merchants use to make into France for racked wines.

RACKOON, in zoology, a species of *URSUS*.

RACONI, a populous town of Italy, in Piedmont, seated in a pleasant plain, on the road from Savillan to Turin, on the rivers Grana and Macra. It belongs to the prince of Carignan, who has a handsome castle here. It is six miles from Savillan, and six from Carignan. E. Long. 7. 46. N. Lat. 44. 39.

RADCLIFFE (Dr John), an English physician of great eminence in his time, born at Wakefield in Yorkshire in 1650. He was educated at Oxford, and enrolled himself upon the physical line; but it was remarkable that he recommended himself more by his ready wit and vivacity, than by any extraordinary acquisitions in learning. He began to practice at Oxford in 1675; but never paid any regard to established rules, which he censured whenever he thought fit, with great freedom and acrimony; and as this drew all the old practitioners upon him, he lived in a continual state of hostility with them. Nevertheless, his reputation increased with his experience; so that, before he had been two years in business, his practice was very extensive among persons of high rank. In 1684 he removed to London, and settled in Bow-street, Covent Garden, where in less than a year he got into prime business.—In 1687 the princess Anne of Denmark made him her physician: yet when her husband and she joined the prince of Orange, Radcliffe, either not choosing to declare himself, or unwilling to favour the measures then in agitation, excused himself from attending them, on the plea of the multitude of his patients. Nevertheless, he was often sent for to King William and other great personages, though he did not incline to be a courtier. He incurred some censure for his treatment of Q. Mary, who died of the small-pox; and soon after lost his place about the princess Anne, by his attachment to his bottle. He also totally lost the favour of K. William by his uncourtly freedom; for, in 1689, when the king showed him his swollen ankles, while the rest of his body was emaciated, and asked him what he thought of them? "Why truly I would not have your majesty's two legs for your three kingdoms," replied Radcliffe. He continued increasing in business and insolence as long as he lived, continually at war with his brethren the physicians; who considered him in no other light than that of an active ingenious empiric, whom constant practice had at length brought to some degree of skill in his profession. He died in 1714; and if he never attempted to write any thing himself, has perpetuated his memory by founding a fine library at Oxford, to preserve the writings of other men.

RADIALIS, the name of two muscles in the arm. See *ANATOMY*, *Table of the Muscles*.

RADIANT, in optics, is any point of a visible object from whence rays proceed.

RADIATED FLOWERS, in botany, are such as have several semistyles set round a disk, in form of a radiant star; those which have no such rays are called *discous flowers*.

RADIATION, the act of a body emitting or diffusing rays of light all round as from a centre.

RADICAL, in general, something that serves as a basis or foundation. Hence physicians talk much of a radical moisture. In grammar, we give the appellation *radical* to primitives, in contradistinction to compounds and derivatives. Algebraists also speak of the radical sign of quantities, which is the character expressing their roots.

RADICLE, that part of the seeds of all plants which upon vegetating becomes their root, and is discoverable by the microscope. See *PLANT*.

RADISH, in botany, See *RAPHANUS*.

RADIUS, in geometry, the semidiameter of a circle, or a right line drawn from the centre to the circumference.

In trigonometry, the radius is termed the whole sine, or sine of 90°. See *SINE*.

RADIUS, in anatomy, the exterior bone of the arm, descending along with the ulna from the elbow to the wrist.

RADNOR, the county-town of Radnorshire, in South Wales. It is a poor little place, distant from London about 150 miles. It is situated near the spring-head of the river Somergil, in a fruitful valley at the bottom of a hill, where there are sheep grazing in abundance. It is a very ancient borough-town, whose jurisdiction extends near 12 miles round about: the government of it is vested in a bailiff and 25 burghesses. Though it is the county-town, the assizes are held at Presteign: it has one privilege, however, that is very extraordinary, besides that of sending one member to parliament; and that is, it keeps a court of pleas for all actions, without being limited to any particular sum. It was formerly fenced with a wall and a strong castle; but both were in a great measure demolished by Owen Glendower, when he assumed the title of Prince of Wales, upon the deposition of King Richard II. W. Long. 2. 45. N. Lat. 52. 10.

RADNORSHIRE, a county of South Wales, is bounded on the north by Montgomeryshire; on the east by Shropshire and Herefordshire; on the south and south-west by Brecknockshire; and on the west by Cardiganshire; extending 30 miles in length and 25 in breadth. This county is divided into six hundreds, in which are contained three market-towns, 52 parishes, about 3160 houses, and 18,960 inhabitants. It is seated in the diocese of Hereford, and sends two members to parliament, one for the county and one for the town of Radnor. The air of this county is in winter cold and piercing. The soil in general is but indifferent; yet some places produce corn, particularly the eastern and southern parts; but in the northern and western, which are mountainous, the land is chiefly stocked with horned cattle, sheep, and goats.

RADIX. See *Root*.

RAFT, a sort of float, formed by an assemblage of various

Radialis
||
Raft.

Rafters
||
Ragusa.

various planks or pieces of timber, fastened together side by side, so as to be conveyed more commodiously to any short distance in a harbour or road than if they were separate. The timber and plank with which merchant-ships are laden, in the different parts of the Baltic Sea, are attached together in this manner, in order to float them off to the shipping.

RAFTERS, in building, are pieces of timber which, standing by pairs on the reason or railing piece, meet in an angle at the top, and form the roof of a building. See ARCHITECTURE.

ROWLEY RAGG, a genus of stones, belonging to the siliceous class. It is of a dusky or dark grey colour, with many small shining crystals, having a granular texture, and acquiring an ochry crust by exposure to the air. The specific gravity is 2748. It becomes magnetic by being heated in an open fire. In a strong fire it melts without addition, but with more difficulty than basalt. It was analysed by Dr Withering, who found that 100 parts of it contain 47.5 of siliceous earth, 32.5 of argil, and 20 of iron.

RAGMAN'S ROLL, Rectius Ragimund's roll, so called from one Ragimund a legate in Scotland, who calling before him all the beneficed clergymen in that kingdom, caused them on oath to give in the *the true value* of their benefices; according to which they were afterwards taxed by the court of Rome; and this roll, among other records, being taken from the Scots by Edward I. was re-delivered to them in the beginning of the reign of Edward III.

RAGOUT, or RAGOO, a sauce, or seasoning, intended to rouse the appetite when lost or languishing.

This term is also used for any high-seasoned dish prepared of flesh, fish, greens, or the like: by stewing them with bacon, salt, pepper, cloves, and the like ingredients. We have ragouts of celery, of endive, asparagus, cock's combs, giblets, craw-fish, &c.

The ancients had a ragout called *garum*, made of the putrified guts of a certain fish kept till it dissolved into a mere sanies, which was thought such a dainty, that, according to Pliny, its price equalled that of the richest perfumes.

RAGSTONE, a genus of stones belonging to the class of siliceous earths. It is of a grey colour; the texture obscurely laminar, or rather fibrous; but the laminæ or fibres consist of a congeries of grains of a quartz appearance, coarse and rough. The specific gravity is 2729; it effervesces with acids, and strikes fire with steel. Mr Kirwan found it to contain a portion of mild calareous earth, and a small proportion of iron. It is used as a whetstone for coarse cutting tools. It is found about Newcastle, and many other parts of England, where there are large rocks of it in the hills.

RAGULED; or RAGGED, in heraldry, jagged or knotted. This term is applied to a cross formed of the trunks of two trees without their branches, of which they show only the stumps. *Raguled* differs from *indented*, in that the latter is regular, the former not.

RAGUSA, an ancient town of Sicily, in the Val-di-Noto, near the river Maulo, 12 miles north of Modica. E. Long. 14. 59. N. Lat. 37. 0.

RAGUSA, a city of Dalmatia, and capital of Ragusen. It is about two miles in circumference, is pretty well built, and strong by situation, having an inaccessible mountain on the land-side, and on the side of the

sea a strong fort. It has an archbishop's see and a republic, and has a doge like that of Venice, but he continues a month only in his office. It carries on a considerable trade with the Turks, and is 60 miles north-west of Scutari, and 110 north of Brindisi. E. Long 18. 10. N. Lat. 42. 50.

RAGUSEN, a territory of Europe in Dalmatia, lying along the coast of the gulph of Venice, about 55 miles in length, and 20 in breadth. It is a republic under the protection of the Turks and Venetians. Ragusa is the capital town.

RAJA, the title of the Indian black princes, the remains of those who ruled there before the Moguls. Some of the rajas are said to preserve their independence, especially in the mountainous parts; but most of them pay an annual tribute to the Mogul. The Indians call them *rai*; the Persians, *raian*, in the plural; and our travellers *rajas*, or *ragias*.

RAJA, the *Ray-Fish*, in ichthyology; a genus belonging to the order of Chondropterygia. There are five spiracula below towards the peak; the body compressed; and the mouth is situated under the head. The most remarkable species are,

1. The batis, or skate: this species is the thinnest in proportion to its bulk of any of the genus, and also the largest, some weighing near 200 pounds. The nose, though not long, is sharp pointed; above the eyes is a set of short spines: the upper part is of a pale brown, sometimes streaked with black: the lower part is white, marked with great numbers of minute black spots. The jaws are covered with small granulated but sharp-pointed teeth. The tail is of a moderate length: near the end are two fins: along the top of it is one row of spines, and on the edges are irregularly dispersed a few others, which makes us imagine with Mr Ray, that in this respect these fish vary, some having one, others more orders of spines on the tail. It is remarked, that in the males of this species the fins are full of spines. Skates generate in March and April; at which time they swim near the surface of the water, several of the males pursuing one female. They adhere so fast together in coition, that the fishermen frequently draw up both together, though only one has taken the bait. The females begin to cast their *purfes*, as the fishermen call them (the bags in which the young are included) in May, and continue doing it till September. In October they are exceedingly poor and thin; but in November they begin to improve, and grow gradually better till May, when they are in the highest perfection. The males go sooner out of season than the females.

2. The oxyrinchus, or sharp-nosed ray, in length near seven feet, and breadth five feet two inches; when just brought on shore it makes a remarkable snorting noise. The nose is very long, narrow, and sharp-pointed, not unlike the end of a spoutoon. The body is smooth, and very thin in proportion to the size; the upper part ash-coloured, spotted with numerous white spots, and a few black ones. The tail is thick; towards the end are two small fins; on each side is a row of small spines, with another row in the middle, which runs some way up the back. The lower part of the fish is quite white. The mouth is very large, and furnished with numbers of small sharp teeth bending inwards. This fish has been supposed to be the *bos* of the an-

cients;

Ragusen,
Raja.

Raja.

* Ulloa's
Voyage,
L. 132.

cients ; which was certainly some enormous species of ray, though we cannot pretend to determine the particular kind. Oppian styles it, *the broadest among fishes* : he adds an account of its fondness of human flesh, and the method it takes of destroying men, by over-laying and keeping them down by its vast weight till they are drowned. Phile (*De propriet. anim.* p. 85.) gives much the same relation. We are inclined to give them credit, since a modern writer, of undoubted authority*, gives the very same account of a fish found in the South Seas, the terror of those employed in the pearl-fishery. It is a species of ray, called there *manta*, or the *quill*, from its surrounding and wrapping up the unhappy divers till they are suffocated ; therefore the negroes never go down without a sharp knife to defend themselves against the assaults of this terrible enemy.

3. The aspera, or rough ray, is found in Loch-Broom in Scotland. The length from the nose to the tip of the tail is two feet nine. The tail is almost of the same length with the body. The nose is very short. Before each eye is a large hooked spine ; and behind each another, beset with lesser. The upper part of the body is of a cinereous brown mixed with white, and spotted with black ; and entirely covered with small spines. On the tail are three rows of great spines : all the rest of the tail is irregularly beset with lesser. The fins and under side of the body are equally rough with the upper. The teeth are flat and rhomboidal.

4. The fullonica, or fuller, derives its Latin name from the instrument fullers make use of in smoothing cloth, the back being rough and spiny. The nose is short and sharp. At the corner of each eye are a few spines. The membrane of nictitation is fringed. Teeth small and sharp. On the upper part of the pectoral fins are three rows of spines pointing towards the back, crooked like those on a fuller's instrument. On the tail are three rows of strong spines : the middle row reaches up part of the back. The tail is slender, and rather longer than the body. The colour of the upper part of the body is cinereous, marked usually with numerous black spots : the lower part is white. This, as well as most other species of rays, vary a little in colour, according to age. This grows to a size equal to the skate. It is common at Scarborough, where it is called the *white hans*, or *gullet*.

5. The shagreen ray increases to the size of the skate ; is fond of launces or sand-eels, which it takes generally as a bait. The form is narrower than that of the common kinds ; the nose long and very sharp ; pupil of the eye sapphire ; on the nose are two short rows of spines ; on the corner of the eyes another of a semicircular form ; on the tail are two rows, continued a little up the back, small, slender, and very sharp : along the sides of the tail is a row of minute spines, intermixed with innumerable little spiculæ. The upper part of the body is of a cinereous brown, covered closely with shagreen-like tubercles, resembling the skin of the dog-fish : the under side of the body is white ; from the nose to the beginning of the pectoral fins is a tuberculated space. The teeth slender, and sharp as needles.

6. The torpedo, cramp-fish, or electric ray, is frequently taken in Torbay : has been once caught off Pembroke, and sometimes near Waterford in Ireland. It is generally taken, like other flat fish, with the trawl ; but there is an instance of its taking the bait. It com-

VOL. XV.

monly lies in water of about 40 fathoms depth ; and in company with the congenerous rays. The torpedo brings forth its young at the autumnal equinox, as affirmed by Aristotle. A gentleman of La Rochelle, on dissecting certain females of this species, the 10th of September, found in the matrices several of the fœtuses quite formed, and nine eggs in no state of forwardness : superfœtation seems therefore to be a property of this fish. The food of the torpedo is fish ; a surmullet and a plaise have been found in the stomach of two of them. The surmullet is a fish of that swiftness, that it was impossible for the torpedo to take it by pursuit. It is probable, therefore, that by their electric stroke they stupify their prey ; yet the crab and sea-leech will venture to annoy them. They will live 24 hours out of the sea ; and but very little longer if placed in fresh water. They inhabit sandy places ; and will bury themselves superficially in it, by flinging the sand over, by a quick flapping of all the extremities. It is in this situation that the torpedo gives his most forcible shock, which throws down the astonished passenger who inadvertently treads upon him. In these seas it grows to a great size, and above 80 pounds weight. The tail is thick and round ; the caudal fin broad and abrupt. The head and body, which are indistinct, are nearly round ; attenuating to extreme thinness on the edges ; below the body, the ventral fins form on each side a quarter of a circle. The two dorsal fins are placed on a trunk of the tail. The eyes are small, placed near each other : behind each is a round spiracle, with six small cutaneous rags on their inner circumference. Mouth small ; teeth minute, spicular. Five openings to the gills, as in others of this genus. The skin everywhere smooth ; cinereous brown above, white beneath. See further the article ELECTRICITY, n° 258—261.

7. The clavata, or thornback, is easily distinguished from the others by the rows of strong sharp spines disposed along the back and tail. In a large one seen by Mr Pennant, were three rows on the back, and five on the tail, all inclining towards its end. On the nose, and on the inner side of the forehead, near the eyes, were a few spines, and others were scattered without any order on the upper part of the pectoral fins. The mouth was small, and filled with granulated teeth : The upper part of the body was of a pale ash colour, marked with short streaks of black, and the skin rough, with small tubercles like shagreen. The belly white, crossed with a strong semilunar cartilage beneath the skin : in general, the lower part was smooth, having only a few spines on each side. The young fish have very few spines on them ; and their backs are often spotted with white, and each spot is encircled with black. This species frequents the sandy shores ; are very voracious, and feed on all sorts of flat fish ; are particularly fond of herrings and sand-eels ; and sometimes eat crustaceous animals, such as crabs. These sometimes weigh 14 or 15 pounds, but with seldom exceed that weight. They begin to generate in June, and bring forth their young in July and August, which (as well as those of the skate) before they are old enough to breed, are called *maids*. The thornback begins to be in season in November, and continues so later than the skate, but the young of both are good at all times of the year.

8. The pastinaca, or sting ray, does not grow to the bulk of the others : The body is quite smooth, of shape almost round, and is of a much greater thickness and

5 F

more

Raja
||
Raillery.

more elevated form in the middle than any other ways, but grows thin towards the edges. The nose is very sharp pointed, but short; the mouth small, and filled with granulated teeth. The irides are of a gold colour: behind each eye the orifice is very large. The tail is very thick at the beginning: the spine is placed about a third the length of the former from the body; is about five inches long, flat on the top and bottom, very hard, sharp pointed, and the two sides thin, and closely and sharply bearded the whole way. The tail extends four inches beyond the end of this spine, and grows very slender at the extremity. These fish are observed to shed their spines, and renew them annually; sometimes the new spine appears before the old one drops off; and the Cornish call this species *cardinal trilobed*, or *three-tailed*, when so circumstanced. The colour of the upper part of the body is a dirty yellow, the middle part of an obscure blue: the lower side white, the tail and spine dusky. The weapon with which nature has armed this fish, hath supplied the ancients with many tremendous fables relating to it. Pliny, Ælian, and Oppian, have given it a venom that affects even the inanimate creation: trees that are struck by it instantly lose their verdure and perish, and rocks themselves are incapable of resisting the potent poison. The enchantress Circe armed her son with a spear headed with the spine of the trygon, as the most irresistible weapon she could furnish him with; and with which he afterwards committed parricide, unintentionally, on his father Ulysses. That spears and darts might, in very early times, have been headed with this bone instead of iron, we have no kind of doubt; that of another species of this fish being still used to point the arrows of some of the South American Indians, and is, from its hardness, sharpness, and beards, a most dreadful weapon. But in respect to its venomous qualities, there is not the least credit to be given to the opinion, though it was believed (as far as it affected the animal world) by Rondeletius, Aldrovand, and others, and even to this day by the fishermen in several parts of the world. It is in fact the weapon of offence belonging to the fish, capable of giving a very bad wound, and which is attended with dangerous symptoms when it falls on a tendinous part or on a person in a bad habit of body. As to any fish having a spine charged with actual poison, it seems very dubious, though the report is sanctified by the name of Linnæus. He instances the *pastinaca*, the *torpedo*, and the *tetrodon lineatus*. The first is incapable of conveying a greater injury than what results from the mere wound; the second, from its electric effluvia; and the third, by imparting a pungent pain like the sting of nettles, occasioned by the minute spines on its abdomen.

RAIANIA, in botany: A genus of the hexandria order, belonging to the dioecia class of plants; and in the natural method ranking under the 11th order, *Samentaceæ*. The male calyx is sexpartite; there is no corolla. The female calyx as in the male, without any corolla; there are three styles; the fruit is roundish with an oblique wing, inferior. There are three species, the *hastata*, *cordata*, and *quinquefolia*.

RAIETEA, one of the South Sea islands, named also **ULIETEA**.

RAIL, in ornithology. See **RALLUS**.

RAILLERY, according to Dr Johnson, means slight satire, or satirical merriment: and a beautiful writer of the last century compares it to a light which

dazzles, and which does not burn. It is sometimes innocent and pleasant, and it should always be so, but it is most frequently offensive. Raillery is of various kinds; there is a serious, severe, and good-humoured raillery; and there is a kind which perplexes, a kind which offends, and a kind which pleases.

To rally well, it is absolutely necessary that kindness run through all you say; and you must ever preserve the character of a friend to support your pretensions to be free with a man. Allusions to past follies, hints to revive what a man has a mind to forget for ever, should never be introduced as the subjects of raillery. This is not to thrust with the skill of fencers, but to cut with the barbarity of butchers. But it is below the character of men of humanity and good-breeding to be capable of mirth, while there is any in the company in pain and disorder.

RAIN, the descent of water from the atmosphere in the form of drops of a considerable size. By this circumstance it is distinguished from dew and fog: in the former of which the drops are so small that they are quite invisible; and in the latter, though their size is larger, they seem to have very little more specific gravity than the atmosphere itself, and may therefore be reckoned hollow spherules rather than drops.

It is universally agreed, that rain is produced by the water previously absorbed by the heat of the sun, or otherwise, from the terraqueous globe, into the atmosphere; but very great difficulties occur when we begin to explain why the water, once so closely united with the atmosphere, begins to separate from it. We cannot ascribe this separation to cold, since rain often takes place in very warm weather; and though we should suppose the condensation owing to the superior cold of the higher regions, yet there is a remarkable fact which will not allow us to have recourse to this supposition. It is certain that the drops of rain increase in size considerably as they descend. On the top of a hill, for instance, they will be small and inconsiderable, forming only a drizzling shower; but at the bottom of the same hill the drops will be excessively large, descending in an impetuous rain; which shows that the atmosphere is disposed to condense the vapours, and actually does so, as well where it is warm as where it is cold.

For some time the suppositions concerning the cause of rain were exceedingly insufficient and unsatisfactory. It was imagined, that when various congeries of clouds were driven together by the agitation of the winds, they mixed, and run into one body, by which means they were condensed into water. The coldness of the upper parts of the air also was thought to be a great means of collecting and condensing the clouds into water; which, being heavier than the air, must necessarily fall down through it in the form of rain. The reason why it falls in drops, and not in large quantities, was said to be the resistance of the air; whereby being broken, and divided into smaller and smaller parts, it at last arrives to us in small drops. But this hypothesis is entirely contrary to almost all the phenomena: for the weather, when coldest, that is, in the time of severe frost, is generally the most serene; the most violent rains also happen where there is little or no cold to condense the clouds; and the drops of rain, instead of being divided into smaller and smaller ones as they approach the earth, are plainly increased in size as they descend.

Rain.

Rain.

Dr Derham accounted for the precipitation of the drops of rain from the vesiculæ being full of air, and meeting with an air colder than they contained, the air they contained was of consequence contracted into a smaller space; and consequently the watery shell rendered thicker, and thus specifically heavier, than the common atmosphere. But it has been shown, that the vesiculæ, if such they are, of vapour, are not filled with air, but with fire, or heat; and consequently, till they part with this latent heat, the vapour cannot be condensed §. Now, cold is not always sufficient to effect this, since in the most severe frosts the air is very often serene, and parts with little or none of its vapour for a very considerable time. Neither can we admit the winds to have any considerable agency in this matter, since we find that blowing upon vapour is so far from condensing it, that it unites it more closely with the air, and wind is found to be a great promoter of evaporation.

According to Rohault, the great cause of rain is the heat of the air; which, after continuing for some time near the earth, is raised on high by a wind, and there thawing the snowy villi or flocks of half-frozen vesiculæ, reduces them to drops; which, coalescing, descend. Here, however, we ought to be informed by what means these vesiculæ are suspended in their half-frozen state; since the thawing of them can make but little difference in their specific gravity, and it is certain that they ascended through the air not in a frozen but in an aqueous state.

Dr Clarke and others ascribe this descent of the rain rather to an alteration of the atmosphere than of the vesiculæ; and suppose it to arise from a diminution of the elastic force of the air. This elasticity, which, they say, depends chiefly or wholly upon terrene exhalations, being weakened, the atmosphere sinks under its burden, and the clouds fall. Now, the little vesicles being once upon the descent, will continue therein, notwithstanding the increase of resistance they every moment meet with. For, as they all tend to the centre of the earth, the farther they fall, the more coalitions they will make; and the more coalitions, the more matter will there be under the same surface; the surface increasing only as the squares, but the solidity as the cubes; and the more matter under the same surface, the less resistance will there be to the same matter. Thus, if the cold, wind, &c. act early enough to precipitate the ascending vesicles before they are arrived at any considerable height, the coalitions being but few, the drops will be proportionably small; and thus is formed a dew. If the vapours be more copious, and rise a little higher, we have a mist or fog. A little higher still, and they produce a small rain; if they neither meet with cold nor wind, they form a heavy thick dark sky. This hypothesis is equally unsatisfactory with the others; for, granting that the descent and condensation of the vapours are owing to a diminution of the atmosphere's elasticity, by what is this diminution occasioned? To say that it is owing to terrene exhalations, is only solving one difficulty by another; since we are totally unacquainted both with the nature and operation of these exhalations. Besides, let us suppose the cause to be what it will, if it acts equally and at once upon all the vapour in the air, then all that vapour must be precipitated at once; and thus,

§ See Chemistry, n° 124, &c.

instead of gentle showers continuing for a considerable length of time, we should have the most violent water-spouts, continuing only for a few minutes, or perhaps seconds, which, instead of refreshing the earth, would drown and lay waste every thing before them.

Since philosophers have admitted the electric fluid to such a large share in the operations of nature, almost all the natural phenomena have been accounted for by the action of that fluid; and rain, among others, has been reckoned an effect of electricity. But this word, unless it is explained, makes us no wiser than we were before; the phenomena of artificial electricity having been explained on principles which could scarce apply in any degree to the electricity of nature: and therefore all the solution we can obtain of the natural appearances of which we speak, comes to this, that rain is occasioned by a moderate electrification, hail and snow by one more violent, and thunder by the most violent of all; but in what manner this electrification is occasioned, hath not yet been explained. Throughout the various parts of this work where electricity hath been occasionally mentioned, the principles of artificial electricity ||, laid down in the treatise appropriated to that subject, have been applied to the solution of the phenomena of nature; those which are necessary to be attended to here are the following:

|| See Electricity, n° 201, 216, &c.

1. The electric fluid and solar light are the same substance in two different modifications.

2. Electricity is the motion of the fluid when running, or attempting to run, in a continued stream from one place to another: heat is when the fluid has no tendency but to vibrate outwards and inwards to and from a centre; or at least when its streams converge to a point or focus.

3. The fluid acting as electricity, like water, or any other fluid, always tends to the place where there is least resistance.

On these three principles may the phenomena of atmospheric electricity, and the descent of rain by its means, be explained as follows:

1. The light or heat of the sun, acting in that peculiar manner which we call *heat*, unites itself with the moisture of the earth, and forms it into vapour, which thus becomes specifically lighter than air, and of consequence ascends in the atmosphere to a certain height.

2. Besides the quantity of light which is thus united to the water, and forms it into vapour, a very considerable quantity enters the earth, where it assumes the nature of electric fluid.

3. As the earth is always full of that fluid, every quantity which enters must displace an equal quantity which is already there.

4. This quantity which is displaced must escape either at a distance from the place where the other enters, or very near it.

5. At whatever place a quantity of electric matter escapes, it must electrify the air above that place where it has escaped; and as a considerable quantity of light must always be reflected from the earth into the atmosphere, where it does not combine with the aqueous vapour, we have thence another source of electricity to the air; as this quantity must undoubtedly assume the action of electric fluid, especially after the action of the sun has ceased. Hence the reason

Rain.

son why in serene weather the atmospherical electricity is always strongest, and rather more so in the night than in the day.

6. From these considerations, we see an evident reason why there must commonly be a difference between the electricity of the earth and that of the atmosphere, excepting when an earthquake is about to ensue. The consequence of this must be, that as the action of the solar light continues to bring down the electric matter, and the earth continues to discharge an equal quantity of it into the atmosphere, some part of the atmosphere must at last become overloaded with it, and attempt to throw it back into the earth. This attempt will be vain, until a vent is found for the electricity at some other place; and as soon as this happens, the electrified atmosphere begins to throw off its superfluous electricity, and the earth to receive it. As the atmosphere itself is a bad conductor, and the more so the drier it is, the electric matter attacks the small aqueous particles which are detained in it by means of the latent heat. These being unable to bear the impetus of the fluid, throw out their latent heat, which easily escapes, and thus makes a kind of vacuum in the electrified part of the atmosphere. The consequences of this are, that the aqueous particles being driven together in large quantity, at last become visible, and the sky is covered with clouds; at the same time a wind blows against these clouds, and, if there is no resistance in the atmosphere, will drive them away.

7. But if the atmosphere all round the cloud is exceedingly electrified, and the earth is in no condition to receive the superfluous fluid excepting in that place which is directly under the cloud, then the whole electricity of the atmosphere for a vast way round will tend to that part only, and the cloud will be electrified to an extreme degree. A wind will now blow against the cloud from all quarters, more and more of the vapour will be extricated from the air by the electric matter, and the cloud will become darker and thicker, at the same time that it is in a manner stationary, as being acted upon by opposite winds; though its size is enlarged with great rapidity by the continual supplies of vapour brought by the winds.

8. The vapours which were formerly suspended invisibly by means of the latent heat are now suspended visibly by the electric fluid, which will not let them fall to the earth, until it is in a condition to receive the electric matter descending with the rain.—It is easy to see, however, that thus every thing is prepared for a violent storm of thunder and lightning as well as rain. The surface of the earth becomes electrified from the atmosphere: but when this has continued for some time, a zone of earth considerably below the surface acquires an electricity opposite to that of the clouds and atmosphere; of consequence the electricity in the cloud being violently pressed on all sides, will at last burst out towards that zone where the resistance is least, as explained under the article **LIGHTNING**.—The vapours now having lost that which supported them, will fall down in rain, if there is not a sufficient quantity of electric matter to keep them in the same state in which they were before: but if this happens to be the case, the cloud will instantly be charged again, while little or no rain will fall; and hence very violent thunder sometimes takes place with-

out any rain at all, or such as is quite inconsiderable in quantity.

9. When the electricity is less violent, the rain will descend in vast quantity, especially after every flash of lightning; and great quantities of electric matter will thus be conveyed to the earth, inasmuch that sometimes the drops have been observed to shine as if they were on fire, which has given occasion to the reports of fiery rain having fallen on certain occasions. If the quantity of electric matter is smaller, so that the rain can convey it all gradually to the ground, there will be rain without any thunder; and the greater the quantity of electricity the more violent will be the rain.

From this account of the causes of rain, we may see the reason why in warm climates the rains are excessive, and for the most part accompanied with thunder; for there the electricity of the atmosphere is immensely greater than it is in cold. We may also see why in certain places, according to the situation of mountains, seas, &c. the rains will be greater than in others, and likewise why some parts of the world are exempted from rain altogether; but as a particular discussion of these would necessarily include an explanation of the causes and phenomena of **THUNDER**, we shall for this reason refer the whole to be treated of under that article.

Whether this theory be just, however, it would be too assuming in us to say. It may admit of dispute, for we must grant that in the very best systems, though an occurrence so frequent, the theory of rain is but very imperfectly understood. Dr James Hutton, Fellow of the Royal Society of Edinburgh, whose speculations are always ingenious, though generally extraordinary, and much out of the common way, gives us a new theory of rain in the first volume of the *Transactions* of that society. It is well known that atmospheric air is capable of dissolving, with a certain degree of heat, a given quantity of water. The Doctor ascertains the ratio of the dissolving power of air, in relation to water, in different degrees of heat; and shows, that by mixing a portion of transparent humid warm air with a portion of cold air, the mixture becomes opaque, and part of the water will be precipitated; or, in other words, the vapour will be condensed into rain. The ratio which he states, however, does not appear to us to be supported by experience. Whether the electricity of the air changes in consequence of its depositing the water dissolved in it, or the change is a cause of this deposition, must remain uncertain; but, in either view, there must be an agent different from heat and cold, since the changes in these respects do not in other operations change the state of electricity. Dr Hutton supposes that heat and solution do not increase by equal increments; but that, in reality, if heat be supposed to increase by equal increments along a straight line, solution will be expressed by ordinates to a curve whose convex side is turned towards that line. That the power of solution is not increased in the same ratio with heat, is, however, hypothetical, except when we rise pretty high in the scale, when its proportional increase is a little doubtful: and it is not, in this paper, supported by experiment. The condensation of the breath in air is not an observation in point, except in air already saturated with vapour. It can amount, in any view, to no more than this, that to render it visible, the heat must be diminished

Rain.

Rain.

minished in a greater proportion than can be compensated by the power of solution in the body of air, in which the portion expired is at first immersed. To explain rain from this cause, we must always suppose a constant diminution of heat to take place at the moment of the condensation of the vapour; but we actually find that the change from a state of vapour to the fluid state is attended with heat; so that rain must at once oppose its own cause, and continued rains would be impossible, without calling in the aid of other causes. From his own system, Dr. Hutton endeavours to explain the regular and irregular seasons of rain, either respecting the generality of its appearance, or the regularity of its return. And to obviate the apparent exceptions of the theory, from the generality of rain, he explains the proportional quantities of rain, and adds a comparative estimate of climates, in relation to rain, with the meteorological observations made in our own climate. As his principle is at least insufficient, and we think erroneous, it would be useless, even were this a proper place for it, to pursue these various branches, which must partake of the errors of the system. In these branches we ought to observe, that there are several just observations, mixed with errors, because evaporation and condensation must at last be the great basis of every theory: the mistakes arise from not being aware of all the causes, and misrepresenting the operation of those which do exist.

In a work entitled *Thoughts on Meteorology*, Volume II. M. de Luc considers very particularly the grand phenomenon of rain, and the numerous circumstances connected with it. He examines the several hypothesis with considerable care; but thinks them, even if admissible, utterly insufficient to account for the formation of rain. The grand question in this inquiry is, What becomes of the water that rises in vapour into the atmosphere? or what state it subsists in there, between the time of its evaporation and its falling down again in rain? If it continues in the state of watery vapour, or such as is the immediate product of evaporation, it must possess the distinctive characters essential to that fluid: it must make the hygrometer move towards humidity, in proportion as the vapour is more or less abundant in the air: on a diminution of heat, the humidity, as shewn by the hygrometer, must increase; and on an increase of the heat the humidity must diminish; and the introduction of other hygroscopic substances, drier than the air, must have the same effect as an augmentation of heat. These are the properties of watery vapour, on every hypothesis of evaporation; and therefore all the water that exists in the atmosphere without possessing these properties, is no longer vapour, but must have changed its nature. M. de Luc shows, that the water which forms rain, though it has ever been considered and reasoned upon as producing humidity, does not possess these properties, and must therefore have passed into another state. See a full account of his reasoning, and the steps by which he proceeded, in the article *METEOROLOGY*, n° 7, &c. As he thinks that the vapour passes into an invisible state in the interval between evaporation and its falling again in rain, and that in that state it is not sensible to the hygrometer, he considers the laws of hygrometry as insufficient for explaining the formation of rain; but he does not pretend to have discovered the immediate cause of the for-

mation of clouds and rain. If it is not in the immediate product of evaporation that rain has its source; if the vapours change their nature in the atmosphere, so as no longer to be sensible to the hygrometer, or to the eye; if they do not become vapour again till clouds appear; and if, when the clouds are formed, no alteration is perceived in the quality of the air—we must acknowledge it to be very probable, that the intermediate state of vapour is no other than air—and that the clouds do not proceed from any distinct fluid contained in the atmosphere, but from a decomposition of a part of the air itself, perfectly similar to the rest.

It appears, to us at least, that M. de Luc's mode of reasoning on this subject agrees better with the phenomena than Dr Hutton's. The Doctor, however, thinks differently, and published answers to the objections of M. de Luc with regard to his theory of rain; to which M. de Luc replied in a letter which was printed in the Appendix to the 81st volume of the *Monthly Review*: but it would extend our article beyond its due bounds, to give a view of this controversy. See VAPOUR, WATER, WEATHER, and WIND.

As to the general quantity of rain that falls, and its proportion in several places at the same time, and in the same place at several times, we have many observations, journals, &c. in the *Memoirs of the French Academy*, the *Philosophical Transactions*, &c. Upon measuring, then, the rain falling yearly, its depth, at a medium, and its proportion in several places, is found as in the following table:

		Inches.
At Townley, in Lancashire, observed by Mr		
Townley	-	42½
Upminster, in Essex, by Dr Derham	-	19½
Zurich, in Swisserland, by Dr Scheuchzer	-	32½
Pisa, in Italy, by Dr Mich. Ang. Tilli	-	43½
Paris, in France, by M. de la Hire	-	19
Lisle, in Flanders, by M. de Vauban	-	24

At Upminster.			At Paris.		
1700	19	Inch. .03	21	Inch. .37	
1701	18	.69	27	.77	
1702	20	.38	17	.45	
1703	23	.99	18	.51	
1704	15	.80	21	.20	
1705	16	.93	14	.82	

From the *Meteorological Journal of the Royal Society*, kept by order of the President and council, it appears that the whole quantity of rain at London, in each of the years specified below, was as follows, viz.

		Inches.
1774	-	26 .328
1775	-	24 .083
1776	-	20 .354
1777	-	25 .371
1778	-	20 .772
1779	-	26 .785
1780	-	17 .313

The quantity of rain in the four following years at London was,

		Inches.
In 1789	-	21 .976
1790	-	16 .052
1791	-	15 .310
1792	-	19 .489

See Philosophical Transactions abridged, vol. iv. p. ii. p. 81, &c. and also Meteorological Journal of the Royal Society, published annually in the Philosophical Transactions.

As to the use of rain, we may observe, that it moistens and softens the earth, and thus fits it for affording nourishment to plants; by falling on high mountains, it carries down with it many particles of loose earth, which serve to fertilize the surrounding valleys, and purifies the air from noxious exhalations, which tend in their return to the earth to meliorate the soil; it moderates the heat of the air; and is one means of supplying fountains and rivers. However, vehement rains in many countries are found to be attended with barrenness and poorness of the lands, and miscarriage of the crops in the succeeding year: and the reason is plain; for these excessive storms wash away the fine mould into the rivers, which carry it into the sea, and it is a long time before the land recovers itself again. The remedy to the famine, which some countries are subject to from this sort of mischief, is the planting large orchards and groves of such trees as bear esculent fruit; for it is an old observation, that in years, when grain succeeds worst, these trees produce most fruit of all. It may partly be owing to the thorough moistening of the earth, as deep as their roots go by these rains, and partly to their trunks stopping part of light mould carried down by the rains, and by this means furnishing themselves with a coat of new earth.

Preternatural RAINS. We have numerous accounts, in the historians of our own as well as other countries, of preternatural rains; such as the raining of stones, of dust, of blood, nay, and of living animals, as young frogs, and the like. We are not to doubt the truth of what those who are authors of veracity and credit relate to us of this kind, so far as to suppose that the falling of stones and dust never happened; the whole mistake is, the supposing them to have fallen from the clouds: but as to the blood and frogs, it is very certain that they never fell at all, but the opinion has been a mere deception of the eyes. Men are extremely fond of the marvellous in their relations; but the judicious reader is to examine strictly whatever is reported of this kind, and is not to suffer himself to be deceived.

There are two natural methods by which quantities of stones and dust may fall in certain places, without their having been generated in the clouds or fallen as rain. The one is by means of hurricanes: the wind which we frequently see tearing off the tiles of houses, and carrying them to considerable distances, being equally able to take up a quantity of stones, and drop them again at some other place. But the other, which is much

the most powerful, and probably the most usual way, is for the eruptions of volcanoes and burning mountains to toss up, as they frequently do, a vast quantity of stones, ashes, and cinders, to an immense height in the air: and these, being hurried away by the hurricanes and impetuous winds which usually accompany those eruptions, and being in themselves much lighter than common stones, as being half calcined, may easily be thus carried to vast distances; and there falling in places where the inhabitants know nothing of the occasion, they cannot but be supposed by the vulgar to fall on them from the clouds. It is well known, that, in the great eruptions of *Ætna* and *Vesuvius*, showers of ashes, dust, and small cinders, have been seen to obscure the air, and overspread the surface of the sea for a great way, and cover the decks of ships; and this at such a distance, as it should appear scarce conceivable that they should have been carried to: and probably, if the accounts of all the showers of these substances mentioned by authors be collected, they will all be found to have fallen within such distances of volcanoes; and if compared as to the time of their falling, will be found to correspond in that also with the eruptions of those mountains. We have known instances of the ashes from *Vesuvius* having been carried thirty, nay, forty leagues, and peculiar accidents may have carried them yet farther. It is not to be supposed that these showers of stones and dust fall for a continuance in the manner of showers of rain, or that the fragments or pieces are as frequent as drops of water; it is sufficient that a number of stones, or a quantity of dust, fall at once on a place, where the inhabitants can have no knowledge of the part from whence they came, and the vulgar will not doubt their dropping from the clouds. Nay, in the canton of *Berne* in *Switzerland*, the inhabitants accounted it a miracle that it rained earth and sulphur upon them at a time that a small volcano terrified them; and even while the wind was so boisterous, and hurricanes so frequent, that they saw almost every moment the dust, sand, and little stones torn up from the surface of the earth in whirlwinds, and carried to a considerable height in the air, they never considered that both the sulphur thrown up by the volcano, and the dust, &c. carried from their feet must fall soon after somewhere. It is very certain that in some of the terrible storms of large hail, where the hail-stones have been of many inches round, on breaking them there have been found what people have called *stones in their middle*; but these observers needed only to have waited the dissolving of one of these hail-stones, to have seen the stone in its centre disunite also, it being only formed of the particles of loose earthy matter, which the water, exhaled by the sun's heat, had taken up in extremely small molecules with it; and this only having served to give an opaque hue to the inner part of the congelation, to which the freezing of the water alone gave the apparent hardness of stone.

The raining of *blood* has been ever accounted a more terrible sight and a more fatal omen than the other preternatural rains already mentioned. It is very certain that nature forms blood nowhere but in the vessels of animals; and therefore showers of it from the clouds are by no means to be credited. Those who suppose that what has been taken for blood has been actually seen falling through the air, have had recourse to flying insects for its origin, and suppose it the eggs or dung of certain

Rain.

Rain.

certain butterflies discharged from them as they were high up in the air. But it seems a very wild conjecture, as we know of no butterfly whose excrements or eggs are of such a colour, or whose abode is so high, or their flocks so numerous, as to be the occasion of this.

It is most probable that these bloody waters were never seen falling; but that people seeing the standing waters blood-coloured, were assured, from their not knowing how it should else happen, that it had rained blood into them. A very memorable instance of this there was at the Hague in the year 1670. Swammerdam, who relates it, tells us, that one morning the whole town was in an uproar on finding their lakes and ditches full of blood, as they thought; and having been certainly full of water the night before, they agreed it must have rained blood in the night: but a certain physician went down to one of the canals, and taking home a quantity of this blood-coloured water, he examined it by the microscope, and found that the water was water still, and had not at all changed its colour; but that it was full of prodigious swarms of small red animals, all alive, and very nimble in their motions, whose colour and prodigious number gave a red tinge to the whole body of the water they lived in, on a less accurate inspection. The certainty that this was the case, did not however persuade the Hollanders to part with the miracle: they prudently concluded, that the sudden appearance of such a number of animals was as great a prodigy as the raining of blood would have been; and are assured to this day, that this portent foretold the scene of war and destruction which Louis XIV. afterwards brought into that country, which had before enjoyed 40 years uninterrupted peace.

The animals which thus colour the water of lakes and ponds are the *pulices arborecentes* of Swammerdam, or the water-fleas with branched horns. These creatures are of a reddish-yellow or flame colour: they live about the sides of ditches, under weeds, and among the mud; and are therefore the less visible, except at a certain time, which is in the end or beginning of June: it is at this time that these little animals leave their recesses to float loose above the water, to meet for the propagation of their species, and by that means become visible in the colour they give the water. This is visible, more or less, in one part or other of almost all standing waters at this season; and it is always at this season that the bloody waters have alarmed the ignorant. See *Pu-LEX Monoculus*.

The raining of frogs is a thing not less wonderful in the accounts of authors who love the marvellous, than those of blood or stones; and this is supposed to happen so often, that there are multitudes who pretend to have been eye-witnesses of it. These rains of frogs always happen after very dry seasons, and are much more frequent in the hotter countries than in the cold ones. In Italy they are very frequent; and it is not uncommon to see the streets of Rome swarming both with young frogs and toads in an instant in a shower of rain; they hopping everywhere between the people's legs as they walk, though there was not the least appearance of them before. Nay, they have been seen to fall through the air down upon the pavements. This seems a strong circumstance in favour of their being rained down from the clouds; but, when strictly examined, it comes to nothing: for these frogs that are seen to fall, are always

found dead, lamed, or bruised by the fall, and never hop about as the rest; and they are never seen to fall, except close under the walls of houses, from the roofs and gutter of which they have accidentally slipped down. Some people, who love to add to strange things yet stranger, affirm that they have had the young frogs fall into their hats in the midst of an open field; but this is idle, and wholly false.

Others, who cannot agree to their falling from the clouds, have tried to solve the difficulty of their sudden appearance, by supposing them hatched out of the egg, or spawn, by these rains. Nay, some have supposed them made immediately out of the dust: but there are unanswerable arguments against all these suppositions. Equivocal generation, or the spontaneous production of animals out of dust, is now wholly exploded. The fall from the clouds must destroy and kill these tender and soft-bodied animals: and they cannot be at this time hatched immediately out of eggs; because the young frog does not make its appearance from the egg in form, but has its hinder legs enveloped in a skin, and is what we call a *tadpole*; and the young frogs are at least 100 times larger at the time of their appearance, than the egg from which they should be hatched.

It is beyond a doubt, that the frogs which make their appearance at this time, were hatched and in being long before: but that the dry seasons had injured them, and kept them sluggishly in holes or coverts; and that all the rain does, is the enlivening them, giving them new spirits, and calling them forth to seek new habitations, and enjoy the element they were destined in great part to live in. Theophrastus, the greatest of all the naturalists of antiquity, has affirmed the same thing. We find that the error of supposing these creatures to fall from the clouds was as early as that author's time; and also that the truth, in regard to their appearance, was as early known; though, in the ages since, authors have taken care to conceal the truth, and to hand down to us the error. We find this venerable sage, in a fragment of his on the generation of animals which appear on a sudden, bantering the opinion, and asserting that they were hatched and living long before. The world owes, however, to the accurate Signior Redi the great proof of this truth, which Theophrastus only has affirmed: for this gentleman, dissecting some of these new-appearing frogs, found in their stomachs herbs and other half-digested food; and, openly showing this to his credulous countrymen, asked them whether they thought that nature, which engendered, according to their opinion, these animals in the clouds, had also been so provident as to engender grass there for their food and nourishment?

To the raining of frogs we ought to add the raining of *grasshoppers* and *locusts*, which have sometimes appeared in prodigious numbers, and devoured the fruits of the earth. There has not been the least pretence for the supposing that these animals descended from the clouds, but that they appeared on a sudden in prodigious numbers. The naturalist, who knows the many accidents attending the eggs of these and other the like animals, cannot but know that some seasons will prove particularly favourable to the hatching them, and the prodigious number of eggs that many insects lay could not but every year bring us such abundance of the young, were they not liable to many accidents, and had not provident nature taken care, as in many plants, to continue the

Rain.

Rain.

Rain.

the species by a very numerous flock of seeds, of which perhaps not one in 500 need take root in order to continue an equal number of plants. As it is thus also in regard to insects, it cannot but happen, that if a favourable season encourage the hatching of all those eggs, a very small number of which alone were necessary to continue the species, we must, in such seasons, have a proportionate abundance of them. There appeared about 50 years ago, in London, such a prodigious swarm of the little beetle we call the *lady-cow*, that the very posts in the streets were everywhere covered with them. But thanks to the progress of philosophy among us, we had no body to assert that it rained cow-ladies, but contented ourselves with saying that it had been a favourable season for their eggs. The prodigious number of a sort of grub which did vast mischief about the same period among the corn and grass by eating off their roots, might also have been supposed to proceed from its having rained grubs by people fond of making every thing a prodigy; but our knowledge in natural history assured us, that these were only the hexapode worms of the common hedge-beetle called the *cock-chaffer*.

The raining of *fishes* has been a prodigy also much talked of in France, where the streets of a town at some distance from Paris, after a terrible hurricane in the night, which tore up trees, blew down houses, &c. were found in a manner covered with fishes of various sizes. Nobody here made any doubt of these having fallen from the clouds; nor did the absurdity of fish, of five or six inches long, being generated in the air, at all startle the people, or shake their belief in the miracle, till they found, upon inquiry, that a very well-stocked fish-pond, which stood on an eminence in the neighbourhood, had been blown dry by the hurricane, and only the great fish left at the bottom of it, all the smaller fry having been tossed into their streets.

Upon the whole, all the supposed marvellous rains have been owing to substances naturally produced on the earth, and either never having been in the air at all, or only carried thither by accident.

In Silesia, after a great dearth of wheat in that country, there happened a violent storm of wind and rain, and the earth was afterwards covered, in many places, with small round seeds. The vulgar cried out that Providence had sent them food, and that it had rained *millets*: but these were, in reality, only the seeds of a species of veronica, or speed-well, very common in that country; and whose seeds being just ripe at that time, the wind had dislodged them from their capsules, and scattered them about. In Britain, we have histories of rains of this marvellous kind, but all fabulous. It was once said to rain *wheat* in Wiltshire; and the people were all alarmed at it as a miracle, till Mr Cole showed them, that what they took for wheat was only the seeds or kernels of the berries of ivy, which being then fully ripe, the wind had dislodged from the sides of houses, and trunks of trees, on which the ivy that produced them crept.

And we even once had a raining of fishes near the coast of Kent in a terrible hurricane, with thunder and lightning. The people who saw small sprats strewn all about afterwards, would have it that they had fallen from the clouds; but those who considered how far the high winds have been known to carry the sea-water, did

not wonder that they should be able to carry small fish with it so small a part of the way.

In the Philosophical Transactions for 1782 we have the following account of a preternatural kind of rain by Count de Gioeni: "The morning of the 24th instant there appeared here a most singular phenomenon. Every place exposed to the air was found wet with a coloured cretaceous grey water, which, after evaporating and filtrating away, left every place covered with it to the height of two or three lines; and all the iron-work that was touched by it became rusty."

"The public, inclined to the marvellous, fancied various causes of the rain, and began to fear for the animals and vegetables."

"In places where rain-water was used, they abstained from it: some suspecting vitriolic principles to be mixed with it, and others predicting some epidemical disorder."

"Those who had observed the explosions of Etna 20 days and more before, were inclined to believe it originated from one of them."

"The shower extended from N. $\frac{1}{4}$ N.E. to S. $\frac{1}{4}$ S.W. over the fields, about 70 miles in a right line from the vertex of Etna."

"There is nothing new in volcanos having thrown up sand, and also stones, by the violent expansive force generated within them, which sand has been carried by the wind to distant regions."

"But the colour and subtilty of the matter occasioned doubts concerning its origin; which increased from the remarkable circumstance of the water in which it came incorporated; for which reasons some other principle or origin was suspected."

"It became, therefore, necessary by all means to ascertain the nature of this matter, in order to be convinced of its origin, and of the effects it might produce. This could not be done without the help of a chemical analysis. To do this then with certainty, I endeavoured to collect this rain from places where it was most probable no heterogeneous matter would be mixed with it. I therefore chose the plant called *brassica capitata*, which having large and turned-up leaves, they contained enough of this coloured water: many of these I emptied into a vessel, and left the contents to settle till the water became clear."

"This being separated into another vessel, I tried it with vegetable alkaline liquors and mineral acids; but could observe no decomposition by either. I then evaporated the water in order to reunite the substances that might be in solution; and touching it again with the aforesaid liquors, it showed a slight effervescence with the acids. When tried with the syrup of violets, this became a pale green; so that I was persuaded it contained a calcareous salt. With the decoction of galls no precipitation was produced."

"The matter being afterwards dried in the shade, it appeared a very subtle fine earth, of a cretaceous colour, but inert, from having been diluted by the rain."

"I next thought of calcining it with a slow fire, and it assumed the colour of a brick. A portion of this being put into a crucible, I applied to it a stronger heat; by which it lost almost all its acquired colour. Again, I exposed a portion of this for a longer time to a very violent heat (from which a vitrification might be expected);

Rain,
Rainbow.

expected); it remained, however, quite soft, and was easily bruised, but returned to its original dusky colour.

"From the most accurate observations of the smoke from the three calcinations, I could not discover either colour or smell that indicated any arsenical or sulphureous mixture.

"Having therefore calcined this matter in three portions, with three different degrees of fire, I presented a good magnet to each: it did not act either on the first or second; a slight attraction was visible in many places on the third: this persuaded me, that this earth contains a martial principle in a metallic form, and not in a vitriolic substance.

"The nature of these substances then being discovered, their volcanic origin appears; for iron, the more it is exposed to violent calcination, the more it is divided by the loss of its phlogistic principle; which cannot naturally happen but in the great chimney of a volcano. Calcareous salt, being a marine salt combined with a calcareous substance by means of violent heat, cannot be otherwise composed than in a volcano.

"As to their dreaded effects on animals and vegetables, every one knows the advantageous use, in medicine, both of the one and the other, and this in the same form as they are thus prepared in the great laboratory of nature.

"Vegetables, even in flower, do not appear in the least macerated, which has formerly happened from only showers of sand.

"How this volcanic production came to be mixed with water may be conceived in various ways.

"Ætna, about its middle regions, is generally surrounded with clouds that do not always rise above its summit, which is 2900 paces above the level of the sea. This matter being thrown out, and descending upon the clouds below it, may happen to mix and fall in rain with them in the usual way. It may also be conjectured, that the thick smoke which the volcanic matter contained might, by its rarefaction, be carried in the atmosphere by the winds over that tract of country; and then cooling so as to condense and become specifically heavier than the air, might descend in that coloured rain.

"I must, however, leave to philosophers (to whom the knowledge of natural agents belongs) the examination and explanation of such phenomena, confining myself to observation and chemical experiments."

RAIN, a well built and fortified town of Bavaria, one of the keys of this electorate, on the Lech, 20 miles west of Ingolstadt. N. Lat. 48. 51. E. Long. 11. 12.

RAIN-Bird. See CUCULUS, n° 8.

RAINBOW. See OPTICS, Part II. Sect. i. § 1.

In the Philosophical Transactions for 1793, we have the following account of two rainbows seen by the Rev. Mr Sturges.

"On the evening of the 9th of July 1792, between seven and eight o'clock, at Alverstoke, near Gosport, on the sea-coast of Hampshire, there came up, in the south-east, a cloud with a thunder-shower; while the sun shone bright, low in the horizon to the north-west.

"In this shower two primary rainbows appeared, AB and AC, not concentric, but touching each other VOL. XV.

at A, in the south part of the horizon; with a secondary bow to each, DE and DF (the last very faint but discernible), which touched likewise at D. Both the primary were very vivid for a considerable time, and at different times nearly equally so; but the bow AB was most permanent, was a larger segment of a circle, and at last, after the other had vanished, became almost a semi-circle; the sun being near setting. It was a perfect calm, and the sea was as smooth as glass.

"If I might venture to offer a solution of this appearance, it would be as follows. I consider the bow AB as the true one, produced by the sun itself; and the other, AC, as produced by the reflection of the sun from the sea, which, in its perfectly smooth state, acted as a speculum. The direction of the sea, between the Isle of Wight and the land, was to the north-west in a line with the sun, as it was then situated. The image reflected from the water, having its rays issuing from a point lower than the real sun, and in a line coming from beneath the horizon, would consequently form a bow higher than the true one AB. And the shores, by which that narrow part of the sea is bounded, would before the sun's actual setting intercept its rays from the surface of the water, and cause the bow AC, which I suppose to be produced by the reflection, to disappear before the other."

The marine or sea bow is a phenomenon which may be frequently observed in a much agitated sea, and is occasioned by the wind sweeping part of the waves, and carrying them aloft; which when they fall down are refracted by the sun's rays, which paint the colours of the bow just as in a common shower. These bows are often seen when a vessel is sailing with considerable force, and dashing the waves around her, which are raised partly by the action of the ship and partly by the force of the wind, and, falling down, they form a rainbow; and they are also often occasioned by the dashing of the waves against the rocks on shore.

In the Philosophical Transactions, it is observed by F. Bourzes, that the colours of the marine rainbow are less lively, less distinct, and of shorter continuance, than those of the common bow; that there are scarce above two colours distinguishable, a dark yellow on the side next the sun, and a pale green on the opposite side. But they are more numerous, there being sometimes 20 or 30 seen together.

To this class of bows may be referred a kind of white or colourless rainbows, which Mentzelius and others affirm to have seen at noon-day. M. Marlotte, in his fourth *Essai de Physique*, says, these bows are formed in mists, as the others are in showers; and adds, that he has seen several both after sun-rising and in the night. The want of colour he attributes to the smallness of the vapours which compose the mist; but perhaps it is rather from the exceeding tenuity of the little vesiculæ of the vapour, which being only little watery pellicles bloated with air, the rays of light undergo but little refraction in passing out of air into them; too little to separate the differently coloured rays, &c. Hence the rays are reflected from them, compounded as they came, that is, white. Rohault mentions * coloured rainbows on the grass; formed by the refractions of the sun's rays in the morning dew. Rainbows have been also produced by the reflection of the sun from a river; and in the Philosophical Transactions, Vol. L. p. 294. we

Rainbow.

* Trait. de
Physique.

Rainbow.

have an account of a rainbow, which must have been formed by the exhalations from the city of London, when the sun had been set 20 minutes, and consequently the centre of the bow was above the horizon. The colours were the same as in the common rainbow, but fainter.

It has often been made a subject of inquiry among the curious how there came to be no rainbow before the flood, which is thought by some to have been the case from its being made a sign of the covenant which the Deity was pleased to make with man after that event. Mr Whitehurst, in his *Inquiry into the Original State and Formation of the Earth*, p. 173, &c. endeavours to establish it as a matter of great probability at least, that the antediluvian atmosphere was so uniformly temperate as never to be subject to storms, tempests, or rain, and of course it could never exhibit a rainbow. For our own part, we cannot see how the earth at that period could do without rain any more than at present; and it appears to us from Scripture equally probable that the rainbow was seen before the flood as after it. It was then, however, made a token of a certain covenant; and it would unquestionably do equally well for that purpose if it had existed before as if it had not.

Lunar RAINBOW. The moon sometimes also exhibits the phenomenon of an iris or rainbow by the refraction of her rays in drops of rain in the night-time. This phenomenon is very rare. In the *Philosophical Transactions* for 1783, however, we have an account of three seen in one year, and all in the same place, communicated in two letters by Marmaduke Tunstall, Esq. The first was seen 27th February 1782, at Greta Bridge, Yorkshire, between seven and eight at night, and appeared "in tolerably distinct colours, similar to a solar one, but more faint: the orange colour seemed to predominate. It happened at full moon; at which time alone they are said to have been always seen. Though Aristotle is said to have observed two, and some others have been seen by Suellius, &c. I can only find two described with any accuracy; viz. one by Plot, in his *History of Oxfordshire*, seen by him in 1675, though without colours; the other seen by a Derbyshire gentleman at Glapwell, near Chesterfield, described by Thoresby, and inserted in N° 331. of the *Philosophical Transactions*: this was about Christmas, 1710, and said to have had all the colours of the Iris Solaris. The night was windy; and though there was then a drizzling rain and dark cloud, in which the rainbow was reflected, it proved afterwards a light frost."

Two others were afterwards seen by Mr Tunstall; one on July the 30th, about 11 o'clock, which lasted about a quarter of an hour, without colours. The other, which appeared on Friday October 18. was "perhaps the most extraordinary one of the kind ever seen. It was first visible about nine o'clock, and continued, though with very different degrees of brilliancy, till past two. At first, though a strongly marked bow, it was without colours; but afterwards they were very conspicuous and vivid in the same form as in the solar, though fainter; the red, green, and purple, were most distinguishable. About twelve it was the most splendid in appearance; its arc was considerably a smaller segment of a circle than a solar; its south-east limb first began to fail, and a considerable time before its final extinction: the wind was very high, nearly due west, most part of

Rainbow, Raisins.

the time, accompanied with a drizzling rain. It is a singular circumstance, that three of these phenomena should have been seen in so short a time in one place, as they have been esteemed ever since the time of Aristotle, who is said to have been the first observer of them, and saw only two in 50 years, and since by Plot and Thoresby, almost the only two English authors who have spoken of them, to be exceeding rare. They seem evidently to be occasioned by a refraction in a cloud or turbid atmosphere, and in general are indications of stormy and rainy weather: so bad a season as the late summer having, I believe, seldom occurred in England. Thoresby, indeed, says, the one he observed was succeeded by several days of fine serene weather. One particular, rather singular, in the second, viz. of July the 30th, was its being six days after the full of the moon; and the last, though of so long a duration, was three days before the full: that of the 27th of February was exactly at the full, which used to be judged the only time they could be seen, though in the *Encyclopedia* there is an account that Weidler observed one in 1719, in the first quarter of the moon, with faint colours, and in very calm weather. No lunar iris, I ever heard or read of, lasted near so long as that on the 18th instant, either with or without colours."

In the *Gentleman's Magazine* for August 1788 we have an account of a lunar rainbow by a correspondent who saw it. "On Sunday evening the 17th of August (says he), after two days, on both of which, particularly the former, there had been a great deal of rain, together with lightning and thunder, just as the clocks were striking nine, 23 hours after full moon, looking through my window, I was struck with the appearance of something in the sky, which seemed like a rainbow. Having never seen a rainbow by night, I thought it a very extraordinary phenomenon, and hastened to a place where there were no buildings to obstruct my view of the hemisphere: here I found that the phenomenon was no other than a lunar rainbow; the moon was truly 'walking in brightness,' brilliant as she could be; not a cloud was to be seen near her; and over-against her, toward the north-west, or perhaps rather more to the north, was a rainbow, a vast arch, perfect in all its parts, not interrupted or broken as rainbows frequently are, but unremittedly visible from one horizon to the other. In order to give some idea of its extent, it is necessary to say, that as I stood toward the western extremity of the parish of Stoke-Newington, it seemed to take its rise from the west of Hampstead, and to the end, perhaps, in the river Lea, the eastern boundary of Tottenham; its colour was white, cloudy, or greyish, but a part of its western leg seemed to exhibit tints of a faint sickly green. I continued viewing it for some time, till it began to rain; and at length the rain increasing, and the sky growing more hazy, I returned home about a quarter or 20 minutes past nine, and in ten minutes came out again; but by that time all was over, the moon was darkened by clouds, and the rainbow of course vanished."

RAINBOW-Stone. See *MOON-Stone*.

RAISINS, grapes prepared by suffering them to remain on the vine till they are perfectly ripe, and then drying them in the sun, or by the heat of an oven.

The

Raisin
||
Raleigh.

The difference between raisins dried in the sun, and those dried in ovens, is very obvious: the former are sweet and pleasant, but the latter have a latent acidity with the sweetness that renders them much less agreeable.

The common way of drying grapes for raisins, is to tie two or three bunches of them together while yet on the vine, and dip them into a hot lixivium of wood-ashes, with a little of the oil of olives in it. This disposes them to shrink and wrinkle; and after this they are left on the vine three or four days separated on sticks in an horizontal situation, and then dried in the sun at leisure, after being cut from the tree. The finest and best raisins are those called in some places *Damascus* and *Jube raisins*; which are distinguished from the others by their size and figure: they are flat and wrinkled on the surface, soft and juicy within, and near an inch long; and, when fresh and growing on the bunch, are of the size and shape of a large olive.

The raisins of the sun, and jar-raisins, are all dried by the heat of the sun; and these are the sorts used in medicine. However, all the kinds have much the same virtues: they are all nutritive and balsamic; they are allowed to be attenuant, are said to be good in nephritic complaints, and are an ingredient in pectoral decoctions: in which cases, as also in all others where astringency is not required of them, they should have the stones carefully taken out.

RAISIN-WINE. See WINE.

RAKKATH (anc. geog.), a town of Upper Galilee, thought to be Tiberias, (Talmud): but this is denied by Reland, who says that Rakkath was a town of the tribe of Naphtali.

RAKE is a well known instrument with teeth, by which the ground is divided. See AGRICULTURE, p. 318.

RAKE also means a loose, disorderly, vicious, and thoughtless fellow.

RAKE of a Ship, is all that part of her hull which hangs over both ends of her keel. That which is before is called the *fore rake*, or *rake forward*, and that part which is at the setting on of the stern-post is called the *rake-aft*, or *afterward*.

RALEIGH (Sir Walter), fourth son of Walter Raleigh, Esq; of Fardel, in the parish of Cornwood in Devonshire, was born in 1552 at Hayes, in the parish of Budley, a farm belonging to his father. About the year 1568, he was sent to Oriel college in Oxford, where he continued but a short time; for in the following year he embarked for France, being one of the hundred volunteers, commanded by Henry Champernon, who, with other English troops, were sent by queen Elizabeth to assist the queen of Navarre in defending the Protestants. In this service he continued for five or six years; after which he returned to London, and probably resided in the Middle Temple. But his enterprising genius would not suffer him to remain long in a state of inactivity. In 1577 or 1578, he embarked for the Low Countries with the troops sent by the queen to assist the Dutch against the Spaniards; and probably shared the glory of the decisive victory over Don John of Austria in 1578. On his return to England, a new enterprise engaged his attention. His half-brother, Sir Humphrey Gilbert, having obtained a patent to plant and inhabit some parts of North Ame-

rica, Mr Raleigh embarked in this adventure; but, meeting with a Spanish fleet, after a smart engagement they returned, without success, in 1579.

The following year, the king of Spain, in conjunction with the pope, having projected a total conquest of the English dominions, sent troops to Ireland to assist the Desmonds in the Munster rebellion. Raleigh obtained a captain's commission under Lord Grey of Wilton, then deputy of Ireland, and embarked for that kingdom; where, by his conduct and resolution, he was principally instrumental in putting an end to the rebellious attempt. He returned to England; and attracted the notice of queen Elizabeth, owing, as we are told in Naunton's *Fragmenta Regalia*, to the following accidental piece of gallantry. The queen, as she was one day taking a walk, being stopped by a *splashy* place in the road, our gallant young soldier took off his new plush mantle, and spread it on the ground. Her majesty trod gently over the fair foot-cloth, surprised and pleased with the adventure. He was a handsome man, and remarkable for his gentility of address.

The queen admitted him to her court, and employed him first as an attendant on the French ambassador Simier on his return home, and afterward to escort the duke of Anjou to Antwerp. During this excursion he became personally known to the prince of Orange; from whom, at his return, he brought special acknowledgments to the queen, who now frequently conversed with him. But the inactive life of a courtier did not suit the enterprising spirit of Mr Raleigh. In the year 1583, he embarked with his brother, Sir Humphrey Gilbert, on a second expedition to Newfoundland, in a ship called the *Raleigh*, which he built at his own expence; but was obliged to return on account of an infectious distemper on board. He was, however, so little affected by this disappointment, that he now laid before the queen and council a proposal for exploring the continent of North America; and in 1584 obtained a patent empowering him to possess such countries as he should discover in that part of the globe. Accordingly Mr Raleigh fitted out two ships at his own expence, which sailed in the month of April, and returned to England about the middle of September, reporting that they had discovered and taken possession of a fine country called *Windangocoa*, to which the queen gave the name of *Virginia*. About this time he was elected knight of the shire for the county of Devon, and soon after received the honour of knighthood; and to enable him to carry on his designs abroad, the queen granted him a patent for licensing the venders of wine throughout the kingdom. In 1585 he sent a fleet of seven ships to Virginia, commanded by his relation Sir Richard Grenville, who left a colony at Roanah of 107 persons, under the government of Mr Lane; and by the establishment of this colony he first imported tobacco into England. See NICOTIANA. In the same year Sir Walter Raleigh obtained a grant of 12,000 acres of the forfeited lands in the county of Cork in Ireland.—About the same time he was made seneschal of the duchy of Cornwall, and warden of the stanneries; and grew into such favour with the queen, that even Leicester was jealous of his influence.

In 1587, he sent another colony of 150 men to Virginia, with a governor, Mr John White, and 12 assistants. About this time we find our knight distinguish-

Raleigh. ed by the titles of *Captain of the queen's guards*, and *Lieutenant general of Cornwall*. From this period to the year 1594, he was continually engaged in projecting new expeditions, sending succours to colonies abroad, defending the kingdom from the insults of the Spaniards, and transacting parliamentary, business, with equal ability and resolution. Whilst thus employed, he was publicly charged, in a libel written by the infamous Jesuit Parsons, with being an Atheist; a groundless and ridiculous imputation. In 1594, he obtained from the queen a grant of the manor of Sherborne in Dorsetshire, where he built a magnificent house: but Sir Walter fell under the queen's displeasure on account of an intrigue with the daughter of Sir Nicholas Throgmorton, one of the maids of honour; however, he married the lady, and lived with her in great conjugal harmony. During his disgrace at court, he projected the conquest of Guiana in South America, and in 1595 failed for that country; of which having taken possession, after defeating the Spaniards who were settled there, he returned to England the same year, and soon after published an account of his expedition. In the following year he was one of the admirals in the successful expedition against Cadiz, under the command of Howard and the earl of Essex; and in 1597 he failed with the same commanders against the Azores. Soon after these expeditions, we find him assiduously engaged in parliamentary business, and a distinguished personage in jousts and tournaments. In 1600 he was sent on a joint embassy with Lord Cobham to Flanders, and at his return made governor of Jersey.

Queen Elizabeth died in the beginning of the year 1603; and with her Raleigh's glory and felicity sunk, never to rise again. Upon the accession of James, Sir Walter lost his interest at court, was stripped of his preferments, and accused of a plot against the king. He was arraigned at Winchester, and, on his trial, insulted by the most shocking brutality by the famous Coke, attorney-general, whose sophistical vociferation influenced the jury to convict him without the least proof of guilt. After a month's imprisonment, however, in daily expectation of his execution, he was reprieved, and sent to the Tower; and his estates were given to Car, earl of Somerset, the king's favourite. During this confinement, he wrote many of his most valuable pieces, particularly his *History of the World*. In March 1615, after 16 years imprisonment, he obtained his liberty, and immediately began to prepare for another voyage to Guiana. In August 1616, the king granted him a very ample commission for that purpose; and in July the year following, he sailed from Plymouth: but, strange as it may appear, it is most certain that the whole scheme was revealed to the Spaniards by the king himself, and thus necessarily rendered abortive.

He returned to England in 1618, where he was soon after seized, imprisoned, and beheaded; not for any pretended misdemeanor on the late expedition, but in consequence of his former attainder. The truth of the matter is, he was sacrificed by the pusillanimous monarch to appease the Spaniards; who, whilst Raleigh lived, thought every part of their dominions in danger. He was executed in Old Palace Yard, and buried in St Margaret's adjoining, in the 66th year of his age. His behaviour on the scaffold was manly, unaffected, cheerful, and easy. Being asked by the executioner which way he would lay his head, he answered, "So the heart

be right, it is no matter which way the head lies." He was a man of admirable parts, extensive knowledge, undaunted resolution, and strict honour and honesty. He was the author of a great many works, some of which have not been printed.

Rallus.

RALLUS, the **RAIL**, in ornithology; a genus belonging to the order of *grallæ*. The beak is thickest at the base, compressed, equal, acute, and somewhat sharp on the back near the point; the nostrils are oval; the feet have four toes, without any web; and the body is compressed. Mr Latham, in his *Index Ornithologicus*, enumerates 24 species, besides some varieties. They are chiefly distinguished by their colour. "These birds (says Buffon) constitute a large family, and their habits are different from those of the other shore-birds, which reside on sands and gravel. The rails, on the contrary, inhabit only the slimy margins of pools and rivers, especially low grounds covered with flags and other large marsh plants. This mode of living is habitual and common to all the species of water-rails. The land rail frequents meadows, and from the disagreeable cry, or rather rattling in the throat of this bird, is derived the generic name. In all the rails, the body is slender, and shrunk at the sides; the tail extremely short; the head small; the bill pretty like that of the gallinaceous kind, though much longer, and not so thick; a portion of the leg above the knee is bare; the three fore-toes without membranes, and very long: they do not, like other birds, draw their feet under their belly in flying, but allow them to hang down: their wings are small and very concave, and their flight is short.— They seem to be more diffused than varied; and nature has produced or transported them over the most distant lands. Captain Cook found them at the Straits of Magellan; in different islands of the southern hemisphere, at Anamoka, at Tanna, and at the isle of Norfolk. In the Society Islands there are two species of rails; a little black spotted one, (*pooa-née*), and a little red-eyed one (*mai-bo*). It appears that the two acolins of Fernandez, which he denominates *water-quails*, are of a species of rails peculiar to the great lake of Mexico.— The colins, which might be confounded with these, are a kind of partridges." The principal are,

1. The aquaticus, or water-rail, is a bird of a long slender body, with short concave wings. It delights less in flying than running: which it does very swiftly along the edges of brooks covered with bushes: as it runs, it every now and then flirts up its tail, and in flying hangs down its legs; actions it has in common with the water-hen. Its weight is four ounces and a half. The length to the end of the tail is 12 inches; the breadth 16. The bill is slender, slightly incurved, one inch three quarters long: the upper mandible black, edged with red; the lower, orange-coloured: the head, hind part of the neck, the back, and coverts of the wings and tail, are black, edged with an olive brown; the throat, breast, and upper part of the belly, are ash-coloured: the sides under the wings as far as the rump, finely varied with black and white bars. The tail is very short, consists of 12 black feathers; the ends of the two middle tipped with rust colour; the feathers immediately beneath the tail white. The legs are placed far behind, and are of a dusky flesh-colour. The toes very long, and divided to their very origin; though the feet are not webbed, it takes the water; will swim on it with much ease, but is often observed

Rallus.

to run along the surface. "Water rails (says Buffon) are seen near the perennial fountains during the greatest part of the winter, yet like the land rails they have their regular migrations. They pass Malta in the spring and autumn. The Viscount de Querhoent saw some 50 leagues off the coasts of Portugal on the 17th of April. They were so fatigued, that they suffered themselves to be caught by the hand (A). Gmelin found these birds in the countries watered by the Don. Belon calls them *black rails*, and says they are every where known, and that the species is more numerous than the red rail, or land rail. The flesh of the water rail is not so delicate as that of the land rail, and has even a marshy taste, nearly like that of the gallinule. It continues the whole year in England."

2. The porzana, or gallinule, is not very frequent in Great Britain, and is said to be migratory. Inhabits the sides of small streams, concealing itself among the bushes. Its length is nine inches; its breadth, 15; its weight, four ounces five drachms. The head is brown, spotted with black; the neck a deep olive, spotted with white: the feathers of the back are black next their shafts, then olive-coloured, and edged with white; the scapulars are olive, finely marked with two small white spots on each web: the legs of a yellowish green. "Its habits (says Buffon) wild, its instinct stupid, the porzana is insusceptible of education, nor is even capable of being tamed. We raised one, however, which lived a whole summer on crumbs of bread and hempseed; when by itself, it kept constantly in a large bowl of water; but if a person entered the closet where it was shut, it ran to conceal itself in a small dark corner, without venting cries or murmurs. In the state of liberty, however, it has a sharp piercing voice, much like the scream of a young bird of prey; and though it has no propensity to society, as soon as one cries, another repeats the sound, which is thus conveyed through all the rest in the district. Like all the rails, it is so obstinately averse to rise, that the sportsman often seizes it with his hand, or fells it with a stick. If it finds a bush in its retreat, it climbs upon it, and from the top of its asylum beholds the dogs brushing along in fault: this habit is common to it and to the water-rail. It dives, swims, and even swims under water, when hard pushed."

"These birds disappear in the depth of winter, but return early in the spring; and even in the month of February they are common in some provinces of France and Italy. Their flesh is delicate, and much esteemed: those, in particular, which are caught in the rice-fields in Piedmont are very fat, and of an exquisite flavour."

3. The crex, crane, or corn-creek, has been supposed by some to be the same with the water-rail, and that it differs only by a change of colour at a certain season of the year: this error is owing to inattention to their characters and nature, both which differ entirely. The bill of this species is short, strong, and thick; formed exactly like that of the water-hen, and makes a general distinction. It never frequents watery places; but is always found among corn, grass, broom, or furze. It quits Britain before winter; but the water rail endures

their sharpest seasons. They agree in their aversion to flight; and the legs, which are remarkably long for the size of the bird, hang down whilst they are on the wing; they trust their safety to their swiftness on foot, and seldom are sprung a second time but with great difficulty. The land rail lays from 12 to 20 eggs, of a dull white colour, marked with a few yellow spots; notwithstanding this, they are very numerous in that kingdom. Their note is very singular; and like the quail, it is decoyed into a net by the imitation of its cry, *crèk crèk crèk*, by rubbing hard the blade of a knife on an indented bone. Most of the names given in different languages to this bird are evidently formed to imitate this singular cry. Hence Turner and some other naturalists have supposed it to be the crex of the ancients; but that term appears to have been applied by the ancients to other birds. Philus gives the crex the epithet of *βραδυπτερος*, or *sluggish-winged*, which would indeed suit the land-rail. Aristophanes represents it as migrating from Lybia: Aristotle says that it is quarrelsome, which may have been attributed to it from the analogy to the quail; but he adds, that the crex seeks to destroy the nests of the blackbird, which cannot apply to the rail, since it never inhabits the woods. Still less is the crex of Herodotus a rail, for he compares its size to that of the ibis, which is ten times larger. The avoet, too, and the teal, have sometimes the cry *crex*, *crex*: and the bird which Belon heard repeating that cry on the banks of the Nile is, according to his account, a species of godwit. Thus the sound represented by the word *crex*, belonging to several species, is not sufficiently precise to distinguish the land-rail.

They are in greatest plenty in Anglesea, where they appear about the 20th of April, supposed to pass over from Ireland, where they abound: at their first arrival it is common to shoot seven or eight in a morning. They are found in most of the Hebrides, and the Orkneys. On their arrival they are very lean, weighing only six ounces; but before they leave that island, grow so fat as to weigh above eight. The feathers on the crown of the head and hind-part of the neck are black, edged with bay colour: the coverts of the wings of the same colour, but not spotted; the tail is short, and of a deep bay: the belly white; the legs ash-coloured.

RALPH (James), a late ingenious historical and political writer, was born, we know not when or where, being first known as a schoolmaster in Philadelphia in North America. He went to England about the beginning of the reign of George I. and wrote some things in the dramatic way, which were not received with great applause: but though he did not succeed as a poet, he was a very ingenious prose-writer. He wrote A History of England, commencing with the Stuarts, which is much esteemed; as were his political essays and pamphlets, some of which were looked upon as master-pieces. His last publication, *The Case of Authors by Profession*, is an excellent and entertaining performance. He died in 1762.

RAM, in zoology. See OVIS.

Battering RAM, in antiquity, a military engine used to

Rallus
||
Ram.

(A) 'I tried (says M. de Querhoent) to raise some: they thrived wonderfully at first, but after a fortnight's confinement their long legs grew paralytic, and the birds could only crawl on their knees; at last they expired.' Gesner says, that having long fed one, he found it to be peevish and quarrelsome."

Ram
Ramesses.

to batter down the walls of besieged places. See *BATTERING Ram*.

RAM's Head, in a ship, is a great block belonging to the fore and main haulyards. It has three shives in it, in which the haulyards are put; and in a hole at the end are reeved the ties.

RAMADAN, a solemn season of fasting among the Mahometans. See *MAHOMETANISM*.

RAMAH (anc. geog.), a town of Benjamin, near Gibeon, (Judges); called *Rama of Saul* (1 Sam. xxii.), six miles from Jerusalem to the north; memorable for the story of the Levite and his concubine: Taken and fortified by Baasha king of Israel, in order to annoy the kingdom of Judah. This Rama is mentioned Isa. x. Jer. xxxi. and Matth. ii. and is to be distinguished from *Rama of Samuel*, 1 Sam. xix. called also *Ramatha*, 1 Sam. i. 19. and *Ramathaim Zophim*, ibid. i. 1. which lay a great way to the west, towards Joppa, near Lydda, 1 Maccab. ii. the birth-place of Samuel; adjoining to the mountains of Ephraim, and the place of his residence, 1 Sam. xv. &c. (Josephus). Called *Ramula* in the lower age, (Gul. Tyrius.) There is here a convent of the Fathers of the Holy Land, inhabited only by Portuguese, Spaniards, and Italians.

RAMATH-MIZPE, (Joshua xiii.); *Ramoth-Maspha*, (Septuagint, Vulgate); *Ramoth in Gilead*, or *Renmath Galiad*, (Seventy); a town in that tract of Gilead called *Maspha*, or *Mizpe*, one of the cities of refuge.

RAMAZZINI (Bernardin), an Italian physician, born at Carpi near Modena in 1633. He was professor of physic in the university of Modena for 18 years; and in 1700 accepted an invitation from Padua, where he was made rector of the college; and died in 1714. His works were collected and published in London, 1716; of which, his treatise *De Morbis Artificum*, "Of the peculiar maladies of artificers," will always be esteemed useful and curious.

RAMEKINS, a fortress of the United Netherlands, on the south coast of the island of Walchevin, in the province of Zeland. One of the cautionary towns given to Queen Elizabeth for the repayment of the charges she had been at for the defence of this republic in its infancy. Four miles east of Flushing; in N. Lat. 51. 34. E. Long. 4. 24.

RAMESES, (anc. geog.); a town built by the Israelites during their bondage in Egypt, and from which the Exodus took place, and which must have been towards and not far from the Arabian Gulph, seeing in the third station the Israelites arrived on its shore.

RAMESES, king of the Lower Egypt when Jacob went thither with his family, in the 1706th year before the Christian era. Ancient authors mention several other kings of Egypt of the same name; and it is thought that one of those princes erected in the temple of the sun at Thebes, the magnificent obelisk which the emperor Constantine caused to be removed to Alexandria in the year 334; and that prince dying, his son Constantius had the obelisk transported from Alexandria to Rome in 352; where it was erected in the grand Circus. Its height was 132 feet. When the Goths sacked the city of Rome in 409, they overthrow this obelisk, which continued buried in the sand till the time of Sixtus V. in 1587, when it was found broken in three pieces; which being joined together, it was set up in the square of St John de Lateran. On the four sides of

this wonderful obelisk are a number of figures and hieroglyphical characters, which, according to the explanation of Ammianus Marcellinus, contain the praises of Rameses.

RAMIFICATION, the production of boughs or branches, or of figures resembling branches.

RAMILLIES, a small village of Brabant, in the Austrian Low Countries, 12 miles north of Namur, and 22 south-east of Brussels. Lat. 50. 51. Long. 4. 48. Famous for the battle fought by the allies commanded by the duke of Marlborough and M. D'Auverquerque, against that of the two crowns, commanded by the Duke of Bavaria and Marshal Villeroy, the 22d of May 1706. See *BRITAIN*, n° 357.

The troops destined to compose the army of the allies being joined at the camp of Borchloon the 20th of May, halted the 21st. On the 22d the army marched from Borchloon in four columns, and posted itself the same day, with the right towards the Mill of Quorem, extending with the left towards Blehen: from this camp was discovered the army of the two crowns, which was encamped with the left at Over-Espen, and the right towards the wood of Chapiaux, Heylissen in their front, and Tirlemont in their rear. It was resolved the same day to march the next morning towards the plain of Meerdorp or Mierdau, to view the posture of the enemies, and determine what would be the most proper means of attacking them according to the movement they should make. To this end, an advanced guard of 500 horse and all the quarter-masters of the army were sent forward on the 23d at break of day.

The same morning about four, the army marched in eight columns towards the afore said plain. The advanced guard and the quarter-masters arrived about eight at the height of Meerdorp or Mierdau; from whence the army of the enemy was seen in motion: a little after it was perceived that the enemy was marching through the plain of Mount St Andrew in four columns, of which information was given to the duke of Marlborough and M. D'Auverquerque, who immediately repaired to the said height; and by the time these generals were arrived there, the head of the enemy's army already appeared at the tomb of Ottomont upon the causeway, near the Mehaigne: whereupon the Duke of Marlborough and M. D'Auverquerque made the army advance with all expedition.

The enemy, as fast as they advanced, ranged in order of battle, with their right towards the tomb of Ottomont upon the Mehaigne, extending with their left to Autr' Eglise; having Tranquiers in front of their right, into which they had thrown several battalions of infantry and 14 squadrons of dragoons, who had dismounted their horses to support them. They had placed many of their infantry and a considerable part of their artillery in the village of Ramillies, which fronted the right of their main body, as well as into the village of Offuz, which fronted the left of their infantry, and into the village of Autr' Eglise, quite on their left. The front between the village of Ramillies and Autr'Eglise was covered by a small stream of water, which rendered the meadows in some places marshes, and also by several roads covered with hedges; which difficulties prevented the allied cavalry of the right wing from coming to action. As fast as the army of the allies arrived it was ranged in order of battle; with the left towards

Bonnef,

Ramifica-
tion,
Ramillies.

Ramillies Bonnet, and the right towards Foltz, and every thing was disposed in order to attack. To this end, four battalions were detached to attack the village of Franquénies, and twelve battalions to attack the village of Ramillies, which were to be supported by the whole infantry.

||
Rampart.

The artillery began to cannonade the enemy at one; at about two, the attack began with the post of Franquénies, where the infantry had the good fortune to drive the enemy from the hedges, where they were advantageously posted, and at the same time all the cavalry of the left wing advanced to attack that of the enemy's right; soon after all was in action. Whilst the cavalry were engaged, the village of Ramillies was likewise attacked, and forced after a vigorous resistance.

The battle lasted about two hours, and was pretty obstinate; but so soon as the allied cavalry had gained ground enough to attack the enemy in flank, they began to give way; at the same time all their infantry were put in disorder, so that the whole retreated in great confusion. The cavalry of their left wing formed a little upon the high ground, between Offuz and Mount St Andrew, to favour their retreat: but after the infantry and cavalry of the right wing of the allies had filed off between the bottom of the village of Ramillies and Offuz, the whole army marched in several columns to attack the enemy anew; but they gave way before the allies could come up with them, and retired in great confusion, some towards the defile of the Abbey De La Ramée and towards Dongelberge, others towards Judogne, and others again towards Hougarde. They were pursued all night so closely that they were obliged to abandon all their artillery and baggage, part of which was found at Judogne and at Hougarde, with their chests of ammunition.

The enemy lost above 30,000 men, 60 cannon, 8 mortars, standards, colours, baggage, &c. the allies about 3000. The rest of the campaign was spent in the sieges of Ostend, Menin, and Aeth. In fourteen days the Duke defeated and dispersed the best appointed army the French ever had, and recovered all Spanish Brabant, the marquisate of the holy Roman empire. The army of the enemy consisted of 76 battalions and 142 squadrons, including the king's household troops (*La Maison du Roi*); and the army of the allies was 74 battalions and 123 squadrons. Considering the importance of the victory, the loss of the allies was very small, not above 1100 being killed, and 2600 wounded.

RAMLA, the modern name of Arimathea. See ARIMATHEA.

RAMMER, an instrument used for driving down stones or piles into the ground; or for beating the earth, in order to render it more solid for a foundation.

RAMMER of a Gun, the *Gun-stick*; a rod used in charging of a gun, to drive home the powder, as also the shot, and the wad which keeps the shot from rolling out.

RAMPANT, in heraldry, a term applied to a lion, leopard, or other beast that stands on its hind legs, and rears up his fore-feet in the posture of climbing, showing only half his face, as one eye, &c. It is different from saliant, in which the beast seems springing forward as if making a fall.

RAMPART, in fortification, is an elevation of earth round a place capable of resisting the cannon of an enemy; and formed into bastions, curtains, &c.

RAMPHASTOS, the *TOUCAN*, in ornithology. **Ramphast.** See **RHAMPHASTOS**.

RAMSAY (Allan), the Scots pastoral poet, was a barber in Edinburgh in the early part of the present century. His taste in poetry, however, has justly raised him to a degree of fame that may in some measure be considered as a recompense for the frowns of fortune. His songs are in universal esteem; as is also the only dramatic performance attributed to him, viz. *Patie and Roger*, or *The Gentle Shepherd*, a Scots pastoral. He died in 1743; and was father to the ingenious Mr Ramsay, a celebrated painter of the present age, and who has likewise distinguished himself by some well-written tracts on various branches of polite literature, particularly the *Investigator*.

RAMSAY (Andrew Michael), generally known by the name of the *Chevalier Ramsay*, was a polite Scots writer, born of a good family at Ayr in 1686. His good parts and learning recommended him to be tutor to the son of the earl of Wemyss; after which, conceiving a disgust at the religion in which he had been educated, he in the same ill humour reviewed other Christian churches; and, finding none to his liking, rested for a while in Deism. While he was in this uncertain state of mind, he went to Leyden; where, falling into the company of one Poirer a mystic divine, he received the infection of mysticism: which prompted him to consult M. Fenelon, the celebrated archbishop of Cambray, who had imbibed principles of the same nature; and who gained him over to the Catholic religion in 1709. The subsequent course of his life received its direction from his friendship and connections with this prelate; and being appointed governor to the duke de Chateau Thierry, and the prince de Turenne, he was made a knight of the order of St Lazarus. He was sent for to Rome by the chevalier de St George, to undertake the education of his children; but he found so many intrigues and dissensions on his arrival there in 1724, that he obtained the Chevalier's leave to return to Paris. He died in 1743, in the office of intendant to the duke of Bouillon, prince de Turenne. The most capital work of his writing is the *Travels of Cyrus*, which has been several times printed in English.

RAMSAY (the Reverend James), so justly celebrated for his philanthropy, was, on the 25th of July 1733, born at Fraserburgh, a small town in the county of Aberdeen, North Britain. His descent was honourable, being, through his father, from the Ramsays of Melrose in Banffshire, and through his mother, from the Ogilvies of Purie in Angus. His parents were of characters the most respectable, but in circumstances by no means affluent. From his earliest years he discovered a serious disposition, and a strong thirst for knowledge; and after passing through the course of a Scotch grammar school education, he was inclined to pursue the studies requisite to fit him for the profession of a clergyman; an inclination with which the wishes of his mother, a woman of eminent piety, powerfully concurred. Several circumstances, however, conspired to divert him for a time from his favourite pursuit.

He was educated in the episcopal persuasion; and having been unhappy enough to lose his father while yet very young, he found, upon his advancing towards the state of manhood, that the joint fortunes of himself and

his

Ramsay. his mother could not bear the expence of a regular education in either of the universities of Oxford or Cambridge, which he doubtless thought absolutely necessary to one who aspired to respectability in the church of England. Yielding therefore to necessity, he resolved to study surgery and pharmacy; and was with this view bound apprentice to Dr Findlay, a physician (A) in Frasersburgh. But though obliged to relinquish for a time his favourite studies, he did not think ignorance excusable in a surgeon more than in a clergyman, or conceive that he could ever become eminent in the profession in which circumstances had placed him, merely by skill in setting a bone or compounding a medicine. He determined therefore, with the full approbation of his master, who very soon discovered his talents for literature, to make himself acquainted with at least the outlines of the liberal arts and sciences; and with this view he repaired in 1750 to the King's College and university of Aberdeen, where he obtained one of the *bursaries* or *exhibitions* which are there annually bestowed upon such candidates for them as display the most accurate knowledge of the Latin language. The small sum of five pounds, however (which none of these bursaries exceed), was still inadequate to the expence of residence in college; but our young student was soon to obtain a more valuable exhibition, and to obtain it likewise by his own merit.

During the long vacation he returned to his master Dr Findlay, and was by him intrusted with a very desperate case in surgery, of which his management may be said to have laid the foundation of his future fortunes. A female servant of one of the judges of the Court of Session, who, when the court was not sitting, resided in the neighbourhood of Frasersburgh, had been so dreadfully gored by a bull, that hardly any hopes were entertained of her recovery; but Mr Ramsay, to whose care she was entirely left, treated the wound with such skilful attention, that, contrary to general expectation, his patient recovered. This attracted the judge's notice, who having informed himself of the young man's circumstances and character, recommended him so effectually to Sir Alexander Ramsay of Balmain, that he presented him with a bursary of 15 pounds a-year, which commenced at the next *session* or *term*, in the same college.

He now prosecuted his studies with comfort; and though he was detained in college a year longer than is usual, being obliged, upon his acceptance of a second bursary, to begin his course anew, he always considered this as a fortunate circumstance, because it gave him the celebrated Dr Reid three years for his preceptor. To that great and amiable philosopher he so recommended himself by his talents, his industry, and his virtues, that he was honoured with his friendship to the day of his death. Nor was it only to his masters that his conduct recommended him; Sir Alexander Ramsay, whom he visited during some of the vacations, was so well pleased with his conversation, that he promised him

another bursary, in his gift, of 25 l. a-year, to commence immediately on the expiration of that which he enjoyed. This promise he performed in the beginning of the year 1755; and at the solicitation of Dr Findlay even paid the money per advance to enable the exhibitor to travel for the purpose of improving himself in his profession.

Thus provided, Mr Ramsay went to London, and studied surgery and pharmacy under the auspices of Dr Macaulay; in whose family he lived for two years, carested and esteemed both by him and by his lady. Afterwards, having passed the usual examination at Surgeon's-hall, he served in his medical capacity for several years in the royal navy; but how long he was continued in the station of a mate, or when and by whom he was first appointed surgeon, we have not been able to learn. We can say, however, upon the best authority, that by his humane and diligent discharge of his duty in either station, he endeared himself to the seamen, and acquired the esteem of his officers.

Of his humanity there is indeed one memorable instance, which must not be omitted. Whilst he acted as surgeon of the *Arundel*, then commanded by Captain (now Vice-admiral Sir Charles) Middleton, a slave-ship on her passage from Africa to the West Indies fell in with the fleet to which the *Arundel* belonged. An epidemical distemper, too common in such vessels, had swept away not only a great number of the unfortunate negroes, but also many of the ship's crew, and among others the surgeon. In this distressed situation the commander of the Guinea ship applied to the English Commodore for medical assistance; but not a surgeon or surgeon's mate in the whole fleet, except Mr Ramsay, would expose himself to the contagion of so dangerous a distemper. Prompted, however, by his own innate benevolence, and fully authorized by his no less benevolent commander, the surgeon of *Arundel*, regardless of personal danger, and trusting in that God to whom mercy is more acceptable than sacrifice, went on board the infected ship, visited all the patients, and remained long enough to leave behind him written directions for their future treatment. If a cup of cold water given in charity be entitled to a reward, how much more such an action as this? But the rewards of Christianity are not immediate. Mr Ramsay indeed escaped the contagion; but on his return to his own ship, just as he had got on the deck, he fell and broke his thigh-bone; by which he was confined to his apartment for ten months, and rendered in a small degree lame through the remainder of his life.

The fearless humanity which he displayed on this occasion gained him the friendship and esteem of Sir Charles Middleton, which no future action of his life had the smallest tendency to impair; but the fracture of his thigh-bone and his subsequent lameness determined him to quit the navy, and once more turn his thoughts towards the church. Accordingly, while the *Arundel* lay at St Christopher's, he opened his views to some

Ramsay.

(A) In the remote towns of Scotland the same man generally acts in the triple capacity of physician, surgeon, and apothecary; and we could mention doctors of physic of the first eminence, who practise thus within forty miles of Edinaburgh.

Ramfay. some of the principal inhabitants of that island, by whom he was so strongly recommended to the bishop of London, that on his coming home with Sir Charles Middleton, who warmly joined in the recommendation, he was admitted into orders; after which he immediately returned to St Christopher's, where he was presented by the governor to two rectories, valued at 700 l. a. year.

As soon as he took possession of his livings, in 1763, he married Miss Rebecca Akers; the daughter of a planter of the best family-connections in the island, and began to regulate his household on the pious plan inculcated in his *Essay on the Treatment and Conversion of the African Slaves in the British Sugar Colonies*. He summoned all his own slaves daily to the prayers of the family, when he took an opportunity of pointing out to them their duty in the plainest terms, reproving those that had done amiss, and commending such as had shown any thing like virtue; but he confessed that his occasions for reproof were more frequent than for commendation. As became his office and character, he inculcated upon others what he practised himself, and knew to be equally the duty of all. "On his first settlement as a minister in the West Indies, he made some public attempts to instruct slaves. He began to draw up some easy, plain discourses for their instruction. He invited them to attend on Sundays, at particular hours. He appointed hours at home to instruct such sensible slaves as would of themselves attend. He repeatedly exhorted their masters to encourage such in their attendance. He recommended the French custom, of beginning and ending work by prayer. But inconceivable is the listlessness with which he was heard, and bitter was the censure heaped on him in return. It was quickly suggested, and generally believed that he wanted to interrupt the work of slaves, to give them time, forsooth, to say their prayers; that he aimed at the making of them Christians, to render them incapable of being good slaves. In one word, he stood, in opinion, a rebel against the interest and majesty of plantership. And as the Jews say, that in every punishment, with which they have been proved, since the bondage of Egypt, there has been an ounce of the golden calf of Horeb; so might he say, that in every instance of prejudice (and they were not a few) with which, till within a year or two of his departure from the country, he was exercised, there was an ounce of his fruitless attempts to improve the minds of slaves. In the bidding prayer, he had inserted a petition for the conversion of those persons. But it was deemed so disagreeable a memento, that several white people, on account of it, left off attending divine service. He was obliged to omit the prayer entirely, to try and bring them back. In short, neither were the slaves, at that time, desirous of being taught, nor were their masters inclined to encourage them."

That he was hurt by this neglect cannot be questioned, for he had a mind benevolent, warm, and irritable; but he still retained many friends amongst the most worthy members of the community: and as he was conscious of having done nothing more than his duty, he consoled himself with reflecting, that those are "blessed whom men revile, and persecute, and speak all manner of evil against falsely, for the sake of the gospel."

Although his serious studies were now theological, he considered himself as answerable to God, his country,

Ramfay. and his own family, for a proper use of every branch of knowledge which he possessed. He therefore took the charge of several plantations around him in the capacity of a medical practitioner; and attended them with unremitting diligence, and with great success. Thus he lived till the year 1777, when relinquishing the practice of physic entirely, he paid a visit to the place of his nativity, which he had not seen since 1755. His mother, whose latter days he had made comfortable by a handsome annuity, had been dead for some years; but he rewarded all who had been attentive to her, or in early life serviceable to himself; and he continued the pension to a sister who had a numerous family, for which her husband was unable to provide.

After remaining three weeks in Scotland, and near a year in England, during which time he was admitted into the confidence of Lord George Germaine, secretary of state for the American department, Mr Ramfay was appointed chaplain to Admiral Barrington, then going out to take a command in the West Indies. Under this gallant officer, and afterwards under Lord Rodney, he was present at several engagements, where displayed a fortitude and zeal for the honour of his country which would not have disgraced the oldest admiral. To the navy, indeed, he seems to have been strongly attached; and he wrote, at an early period of his life, an *Essay on the Duty and Qualifications of a Sea-officer*, with such a knowledge of the service as would have done honour to the pen of the most experienced commander. Of the first edition of this essay the profits were by its benevolent author appropriated to the Magdalen and British lying-in hospitals, as those of the second and third (which last was published about the period of which we now write) were to the maritime school, or, in the event of its failure, to the marine society.

Although caressed by both the admirals under whom he served, and having such influence with the latter as to be able to render essential services to the Jews and other persons whom he thought harshly treated at the capture of St Eustatius, Mr Ramfay once more quitted the sea-service, and retired to his pastoral charge in the Island of St Christopher's. There, however, though the former animosities against him had entirely subsided, and though his friendship was now solicited by every person of consequence in the island, he remained but a little while. Sick of the life of a planter and of the prospect of slavery around him, he resigned his living, bade adieu to the island, and returned to England with his wife and family in the end of the year 1781. Immediately on his arrival, he was, through the interest of his steady friend Sir Charles Middleton, presented to the livings of Tetton and Nettlestead in the county of Kent.

Here he was soon determined, by the advice of those whom he most respected, to publish an *Essay*, which had been written many years before, *on the Treatment and Conversion of African Slaves in the British Sugar Colonies*. The controversy in which this publication involved him, and the acrimony with which it was carried on, are so fresh in the memory of all our readers, that no man who thinks of the narrow limits within which our biographical articles must be confined, will blame us for not entering into a detail of the particulars.—Torrents of obloquy were poured upon the benevolent author by writers who were unfair enough to conceal

Ramsay,
Ramsden's
Machine.

their names; and it must be confessed, that his replies abounded with sarcasms, which the most rational friends to the cause which he supported would not have been sorry to see blotted from his pages. The provocation, however, which he received was great; and Mr Ramsay, though an amiable, virtuous, and pious man, had a warmth of temper, which, though not deserving of praise, will be censured by none who reflect on the frailties of our common nature. That the particular calumnies propagated against him on this occasion were wholly groundless, it is impossible to doubt, if we admit him to have been possessed of common understanding. When some years ago a story was circulated, of Swift's having, when prebendary of Kilroot, been convicted before a magistrate of an attempt to commit a rape on the body of one of his parishioners, it was thought a sufficient confutation of the calumny to put the retailer of it in mind, that the dean of St Patrick's, though detested by the most powerful faction in the kingdom, lampooned without dread, and with great severity, the dean of Ferns for the very crime of which, had this anecdote been true, he must have been conscious that all Ireland knew himself to be guilty? Such conduct cannot be reconciled to common sense. Had Swift been a ravisher, though he might have been penitent, and reasoned in general terms against giving way to such licentious passions, he would never have satyrised *a particular person* for the crime of which he himself stood convicted. In like manner, had Mr Ramsay been a tyrant to his own slaves, though he might have argued against slavery in the abstract, on the broad basis of virtue and religion, he never could have arraigned for similar cruelty a number of individuals in the very island which witnessed his own enormities.

But the melancholy part of the narrative is behind. The agitation given to his mind by these calumnies, and the fatigues he underwent in his endeavours to rescue from misery the most helpless portion of the human race, contributed to shorten a life in no common degree useful. He had been for some time afflicted with a pain in his stomach, for which he was prevailed upon, tho' with great reluctance, to try the effects of air and exercise, by attempting a journey of 100 miles. But in London, being seized with a violent vomiting of blood, he was unable either to proceed or to be removed home; and in the house of Sir Charles Middleton he ended his days, on the 20th of July 1789, amidst the groans of his family, and the tears of many friends.— Thus died a man, of whom it is not too much to say, that "the blessing of many that were ready to perish came upon him;" for whatever be the fate of the slave-trade (see SLAVERY), it is certain that his writings have contributed much to meliorate the treatment of slaves. He left behind him a widow and three daughters: and his works, besides those to which we have alluded, consist of a volume of *Sea-sermons*, preached on board his majesty's ship the Prince of Wales, which show him to have been a master of true pulpit-eloquence; and a *Treatise on Signals*, which was certainly written, and we think printed, though we know not whether it was ever published.

RAMSDEN'S MACHINE for Dividing MATHEMATICAL INSTRUMENTS, is a late invention, by which these divisions can be performed with exceeding great accuracy, such as would formerly have been deemed in-

credible. On discovering the method of constructing this machine, its inventor, Mr Ramsden of Piccadilly, received 615 l. from the commissioners of longitude; engaging himself to instruct a certain number of persons, not exceeding ten, in the method of making and using this machine from the 28th October 1775 to 28th October 1777: also binding himself to divide all octants and sextants by the same engine, at the rate of three shillings for each octant, and six shillings for each brass sextant, with Nonius's divisions to half minutes, for as long time as the commissioners should think proper to let the engine remain in his possession. Of this sum of 615 l. paid to Mr Ramsden, 300 l. was given him as a reward for the improvement made by him in discovering the engine, and the remaining 315 l. for his giving up the property of it to the commissioners. The following description of the engine, is that given upon oath by Mr Ramsden himself.

"This engine consists of a large wheel of bell-metal, supported on a mahogany stand, having three legs, which are strongly connected together by braces, so as to make it perfectly steady. On each leg of the stand is placed a conical friction-pulley, whereon the dividing-wheel rests: to prevent the wheel from sliding off the friction-pulleys, the bell-metal centre under it turns in a socket on the top of the stand.

"The circumference of the wheel is ratched or cut (by a method which will be described hereafter) into 2160 teeth, in which an endless screw acts. Six revolutions of the screw will move the wheel a space equal to one degree.

"Now a circle of brass being fixed on the screw arbor, having its circumference divided into 60 parts, each division will consequently answer to a motion of the wheel of 10 seconds, six of them will be equal to a minute, &c.

"Several different arbors of tempered steel are truly ground into the socket in the centre of the wheel. The upper parts of the arbors that stand above the plane are turned of various sizes, to suit the centres of different pieces of work to be divided.

"When any instrument is to be divided, the centre of it is very exactly fitted on one of these arbors; and the instrument is fixed down to the plane of the dividing wheel, by means of screws, which fit into holes made in the radii of the wheel for that purpose.

"The instrument being thus fitted on the plane of the wheel, the frame which carries the dividing-point is connected at one end by finger-screws with the frame which carries the endless screw; while the other end embraces that part of the steel arbor, which stands above the instrument to be divided, by an angular notch in a piece of hardened steel; by this means both ends of the frame are kept perfectly steady and free from any shake.

"The frame carrying the dividing-point, or tracer, is made to slide on the frame which carries the endless screw to any distance from the centre of the wheel as the radius of the instrument to be divided may require, and may be there fastened by tightening two clamps; and the dividing-point or tracer being connected with the clamps by the double-jointed frame, admits a free and easy motion towards or from the centre for cutting the divisions, without any lateral shake.

"From what has been said, it appears, that an instrument

Ramsden's
Machine.

Ramsden's
Machine.

Instrument thus fitted on the dividing-wheel may be moved to any angle by the screw and divided circle on its arbor, and that this angle may be marked on the limb of the instrument with the greatest exactness by the dividing-point or tracer, which can only move in a direct line tending to the centre, and is altogether freed from those inconveniences that attend cutting by means of a straight edge. This method of drawing lines will also prevent any error that might arise from an expansion or contraction of the metal during the time of dividing.

"The screw-frame is fixed on the top of a conical pillar, which turns freely round its axis, and also moves freely towards or from the centre of the wheel, so that the screw-frame may be entirely guided by the frame which connects it with the centre: by this means any excentricity of the wheel and the arbor would not produce any error in the dividing; and, by a particular contrivance (which will be described hereafter), the screw when pressed against the teeth of the wheel always moves parallel to itself; so that a line joining the centre of the arbor and the tracer continued, will always make equal angles with the screw.

Plate
ccccxxxiii. Figure 1. represents a perspective view of the engine.

Plate
ccccxxxiv. "Fig. 2. is a plan, of which fig. 3. represents a section on the line *mn*.

"The large wheel A is 45 inches in diameter, and has ten radii, each being supported by edge-bars, as represented in fig. 3. These bars and radii are connected by the circular ring B, 24 inches in diameter and 3 deep; and, for greater strength, the whole is cast in one piece in bell-metal.

"As the whole weight of the wheel A rests on its ring B, the edge-bars are deepest where they join it; and from thence their depth diminishes, both towards the centre and the circumference, as represented in fig. 3.

"The surface of the wheel A was worked very even and flat, and its circumference turned true. The ring C, of fine brass, was fitted very exactly on the circumference of the wheel; and was fastened thereon with screws, which, after being screwed as tight as possible, were well rivetted. The face of a large chuck being turned very true and flat in the lathe, the flattened surface A of the wheel was fastened against it with hold-fasts; and the two surfaces and circumference of the ring C, a hole through the centre and the plane part round (b) it, and the lower edge of the ring B, were turned at the same time.

"D is a piece of hard bell-metal, having the hole, which receives the steel-arbor (d), made very straight and true. This bell-metal was turned very true on an arbor; and the face, which rests on the wheel at (b), was turned very flat, so that the steel arbor (d) might stand perpendicular to the plane of the wheel: this bell-metal was fastened to the wheel by six steel screws (l).

"A brass socket Z is fastened on the centre of the mahogany stand, and receives the lower part of the bell-metal piece D, being made to touch the bell-metal in a narrower part near the mouth, to prevent any obliquity of the wheel from bending the arbor: good fitting is by no means necessary here; since any shake

in this socket will produce no bad effect, as will appear hereafter when we describe the cutting frame.

"The wheel was then put on its stand, the lower edge of the ring B resting on the circumference of three conical friction-pulleys W, to facilitate its motion round its centre. The axis of one of these pulleys is in a line joining the centre of the wheel and the middle of the endless screw, and the other two placed so as to be at equal distances from each other.

"F is a block of wood strongly fastened to one of the legs of the stand; the piece (g) is screwed to the upper side of the block, and has half holes, in which the transverse axis (h) turns: the half holes are kept together by the screws (i).

"The lower extremity of the conical pillar P terminates in a cylindrical steel-pin (k), which passes through and turns in the transverse axis (h), and is confined by a cheek and screw.

"To the upper end of the conical pillar is fastened the frame G, in which the endless screw turns: the pivots of the screw are formed in the manner of two frustums of cones joined by a cylinder, as represented at X. These pivots are confined between half poles, which press only on the conical parts, and do not touch the cylindric parts: the half holes are kept together by screws (a), which may be tightened at any time, to prevent the screw from shaking in the frame.

"On the screw-arbor is a small wheel of brass K, having its outside edge divided into 60 parts, and numbered at every 6th division with 1, 2, &c. to 10. The motion of this wheel is shown by the index (y) on the screw-frame G.

"H represents a part of the stand, having a parallel slit in the direction towards the centre of the wheel, large enough to receive the upper part of the conical brass pillar P, which carries the screw and its frame: and as the resistance, when the wheel is moved by the endless screw, is against that side of the slit H which is towards the left hand, that side of the slit is faced with brass, and the pillar is pressed against it by a steel spring on the opposite side: by this means the pillar is strongly supported laterally, and yet the screw may be easily pressed from or against the circumference of the wheel, and the pillar will turn freely on its axis to take any direction given it by the frame L.

"At each corner of the piece I are screws (n) of tempered steel, having polished conical points: two of them turn in conical holes in the screw-frame near (o), and the points of the other two screws turn in holes in the piece Q; the screws (p) are of steel, which being tightened, prevent the conical pointed screws from unturning when the frame is moved.

"L is a brass frame, which serves to connect the endless screw, its frame, &c. with the centre of the wheel: each arm of this frame is terminated by a steel screw, that may be passed through any of the holes (q) in the piece Q, as the thickness of work to be divided on the wheel may require, and are fastened by the finger-nuts (r).

"At the other end of this frame is a flat piece of tempered steel (b), wherein is an angular notch: when the endless screw is pressed against the teeth on the circumference of the wheel, which may be done by turning the finger-screw S, so as to press against the spring (t),

Fig. 3.

Ramfsden's Machine. (d). This end of the frame may be raised or depressed by moving the prismatic slide (e), which may be fixed at any height by the four steel-screws (v).
Fig. 1, 2, 6.

Fig. 3. "The bottom of this slide has a notch (k), whose plane is parallel to the endless-screw; and by the point of the arbor (d) resting in this notch, this end of the frame is prevented from tilting. The screw S is prevented from unturning, by tightening the fingernut (w).
Fig. 1, 2.

"The teeth on the circumference of the wheel were cut by the following method:

"Having considered what number of teeth on the circumference would be most convenient, which in this engine is 2160, or 360 multiplied by 6, I made two screws of the same dimensions, of tempered steel, in the manner hereafter described, the interval between the threads being such as I knew by calculation would come within the limits of what might be turned off the circumference of the wheel: one of these screws, which was intended for ratching or cutting the teeth, was notched across the threads, so that the screw, when pressed against the edge of the wheel and turned round, cut in the manner of a saw. Then having a segment of a circle a little greater than 60 degrees, of about the same radius with the wheel, and the circumference made true, from a very fine centre, I described an arch near the edge, and set off the chord of 60 degrees on this arch. This segment was put in the place of the wheel, the edge of it was ratched, and the number of revolutions and parts of the screw contained between the interval of the 60 degrees were counted. The radius was corrected in the proportion of 360 revolutions, which ought to have been in 60 degrees, to the number actually found; and the radius, so corrected, was taken in a pair of beam-compasses: while the wheel was on the lath, one foot of the compasses was put in the centre, and with the other a circle was described on the ring; then half the depth of the threads of the screw being taken in dividers, was set from this circle outwards, and another circle was described cutting this point; a hollow was then turned on the edge of the wheel of the same curvature as that of the screw at the bottom of the threads: the bottom of this hollow was turned to the same radius or distance from the centre of the wheel, as the outward of the two circles beforementioned.

Fig 3. "The wheel was now taken off the lath; and the bell-metal piece D was screwed on as before directed, which after this ought not to be removed.

Fig. 1, 2, 3. "From a very exact centre a circle was described on the ring C, about $\frac{1}{8}$ of an inch within where the bottom of the teeth would come. This circle was divided with the greatest exactness I was capable of, first into five parts, and each of these into three. These parts were then bisected four times: (that is to say) supposing the whole circumference of the wheel to contain 2160 teeth, this being divided into five parts, each would contain 432 teeth; which being divided into three parts, each of them would contain 144; and this space

bisected four times would give 72, 36, 18, and 9: there. Ramfsden's Machine. fore each of the last divisions would contain nine teeth. But, as I was apprehensive some error might arise from quinquesection and trisection, in order to examine the accuracy of the divisions, I described another circle on the ring C, $\frac{1}{8}$ inch within the former, and divided it by continual bisections, as 2160, 1080, 540, 270, 135, 67½, and 33½; and as the fixed wire (to be described presently) crossed both the circles, I could examine their agreement at every 135 revolutions; (after ratching, could examine it at every 33½): but, not finding any sensible difference between the two sets of divisions, I, for ratching, made choice of the former; and, as the coincidence of the fixed wire with an intersection could be more exactly determined than with a dot or division, I therefore made use of intersections in both circles before described.

"The arms of the frame L were connected by a thin piece of brass of $\frac{1}{4}$ of an inch broad, having a hole in the middle of $\frac{1}{8}$ of an inch in diameter; across this hole a silver wire was fixed exactly in a line to the centre of the wheel; the coincidence of this wire with the intersections was examined by a lens $\frac{7}{8}$ inch focus, fixed in a tube which was attached to one of the arms L (A). Now a handle or winch being fixed on the end of the screw, the division marked 10 on the circle K was set to its index, and, by means of a clamp and adjusting screw for that purpose, the intersection marked 1 on the circle C was set exactly to coincide with the fixed wire; the screw was then carefully pressed against the circumference of the wheel, by turning the finger-screw S; then, removing the clamp, I turned the screw by its handle 9 revolutions, till the intersection marked 240 came nearly to the wire; then, unturning the finger-screw S, I released the screw from the wheel, and turned the wheel back till the intersection marked 2 exactly coincided with the wire, and, by means of the clamp beforementioned, the division 10 on the circle being set to its index, the screw was pressed against the edge of the wheel by the finger-screw S; the clamps were removed, and the screw turned nine revolutions till the intersection marked 1 nearly coincided with the fixed wire; the screw was released from the wheel by unturning the finger-screw S. as before, the wheel was turned back till the intersection 3 coincided with the fixed wire; the division 10 on the circle being set to its index, the screw was pressed against the wheel as before, and the screw was turned 9 revolutions, till the intersection 2 nearly coincided with the fixed wire, and the screw was released; and I proceeded in this manner till the teeth were marked round the whole circumference of the wheel. This was repeated three times round, to make the impression of the screw deeper. I then ratched the wheel round continually in the same direction without ever disengaging the screw; and, in ratching the wheel about 300 times round, the teeth were finished.

"Now it is evident, if the circumference of the wheel was even one tooth or ten minutes greater than the screw would require, this error would in the first instance

(A) The intersections are marked for the sake of illustration, though properly invisible, they lying under the brass plate.

Ramfden's
Machine.

stance be reduced to $\frac{1}{4}$ part of a revolution, or two seconds and a half; and these errors or inequalities of the teeth were equally distributed round the wheel at the distance of nine teeth from each other. Now, as the screw in ratching had continually hold of several teeth at the same time, and, these constantly changing, the abovementioned inequalities soon corrected themselves, and the teeth were reduced to a perfect equality. The piece of brass which carries the wire was now taken away, and the cutting screw was also removed, and a plain one (hereafter described) put in its place: on one end of the screw is a small brass circle, having its edge divided into 60 equal parts, and numbered at every sixth division, as beforementioned. On the other end of the screw is a ratchet-wheel C, having 60 teeth, covered by the hollowed circle (d), which carries two clicks that catch upon the opposite sides of the ratchet when the screw is to be moved forwards. The cylinder S turns on a strong steel arbor E, which passes through and is firmly screwed to the piece Y: this piece, for greater firmness, is attached to the screw-frame G by the braces (v): a spiral groove or thread is cut on the outside of the cylinder S, which serves both for holding the string, and also giving motion to the lever J on its centre by means of a steel tooth (n), that works between the threads of the spiral. To the lever is attached a strong steel pin (m), on which a brass socket (r) turns: this socket passes through a slit in the piece (p), and may be tightened in any part of the slit by the finger-nut (f): this piece serves to regulate the number of revolutions of the screw for each tread of the treadle R.

Fig. 5:

Fig. 4.

Fig. 1.
Fig. 1.

Fig. 4.

Fig. 1.

Fig. 1.

Fig. 1 & 4.

Fig. 1, 2, 6.

"T is a brass box containing a spiral spring; a strong gut is fastened and turned three or four times round the circumference of this box; the gut then passes several times round the cylinder S, and from thence down to the treadle R. Now, when the treadle is pressed down, the string pulls the cylinder S round its axis, and the clicks catching hold of the teeth on the ratchet carry the screw round with it, till, by the tooth (n) working in the spiral groove, the lever J is brought near the wheel (d), and the cylinder stopped by the screw-head (x) striking on the top of the lever J; at the same time the spring is wound up by the other end of the gut passing round the box T. Now, when the foot is taken off the treadle, the spring unbending itself pulls back the cylinder, the clicks leaving the ratchet and screw at rest till the piece (t) strikes on the end of the piece (p): the number of revolutions of the screw at each thread is limited by the number of revolutions the cylinder is allowed to turn back before the stop strikes on the piece (p).

"When the endless screw was moved round its axis with a considerable velocity, it would continue that motion a little after the cylinder S was stopped: to prevent this, the angular lever α was made; that when the lever J comes near to stop the screw (x), it, by a small chamfer, presses down the piece α of the angular lever; this brings the other end λ of the same lever forwards, and stops the endless screw by the steel pin μ striking upon the top of it: the foot of the lever is raised again by a small spring pressing on the brace (v).

"D, two clamps, connected by the piece ν , slide one on each arm of the frame L, and may be fixed at

pleasure by the four finger-screws ϵ , which press against steel springs to avoid spoiling the arms: the piece (q) is made to turn without shake between two conical pointed screws (f), which are prevented from unturning by tightening the finger-nuts N.

"The piece M is made to turn on the piece (q), by the conical pointed screws (f) resting in the hollow centers (e).

"As there is frequent occasion to cut divisions on inclined planes, for that purpose the piece γ , in which the tracer is fixed, has a conical axis at each end, which turn in half holes: when the tracer is set to any inclination, it may be fixed there by tightening the steel screws β .

Description of the Engine by which the endless screw of the Dividing Engine was cut.

"Fig. 9. represents this engine of its full dimensions seen from one side.

"Fig. 8. the upper side of the same as seen from above.

"A represents a triangular bar of steel, to which the triangular holes in the pieces B and C are accurately fitted, and may be fixed on any part of the bar by the screws D.

"E is a piece of steel whereon the screw is intended to be cut; which, after being hardened and tempered, has its pivots turned in the form of two frustums of cones, as represented in the drawings of the dividing engine (fig. 5.). These pivots were exactly fitted to the half holes F and T, which were kept together by the screws Z.

"H represents a screw of untempered steel, having a pivot I, which turns in the hole K. At the other end of the screw is a hollow centre, which receives the hardened conical point of the steel pin M. When this point is sufficiently pressed against the screw, to prevent its shaking, the steel pin may be fixed by tightening the screws Y.

"N is a cylindric nut, moveable on the screw H; which, to prevent any shake, may be tightened by the screws O. This nut is connected with the saddle-piece P by means of the intermediate universal joint W, through which the arbor of the screw H passes. A front view of this piece, with a section across the screw arbor, is represented at X. This joint is connected with the nut by means of two steel slips S, which turn on pins between the cheeks T on the nut N. The other ends of these slips S turn in like manner on pins (a). One axis of this joint turns in a hole in the cock (b), which is fixed to the saddle-piece; and the other turns in a hole (d), made for that purpose in the same piece on which the cock (b) is fixed. By this means, when the screw is turned round, the saddle-piece will slide uniformly along the triangular bar A.

"K is a small triangular bar of well-tempered steel, which slides in a groove of the same form on the saddle-piece P. The point of this bar or cutter is formed to the shape of the thread intended to be cut on the endless screw. When the cutter is set to take proper hold of the intended screw, it may be fixed by tightening the screw (e), which presses the two pieces of brass G upon it.

"Having measured the circumference of the dividing-wheel, I found it would require a screw about one thread

Ramsey. thread in a hundred coarser than the guide-screw H. The wheels on the guide-screw arbor H, and that on the steel E, on which the screw was to be cut, were proportioned to each other to produce that effect, by giving the wheel L 198 teeth, and the wheel Q 200. These wheels communicated with each other by means of the intermediate wheel R, which also served to give the threads on the two screws the same direction.

"The saddle-piece P is confined on the bar A by means of the pieces (g), and may be made to slide with a proper degree of tightness by the screws (n)."

For Ramiden's equatorial or portable observatory, see OPTICS, n° 102. and ASTRONOMY, n° 504. See also a long account of an equatorial instrument made by Mr Ramlden by the direction of Sir George Shuckburgh in the Philosophical Transactions for 1793, art. x. p. 67. In this instrument the circle of declinations is four feet in diameter, and may be observed nearly to a second. The glass is placed between six pillars, which form the axis of the machine, and turn round by two pivots placed on two blocks of stone. See also BAROMETER.

RAMSEY, a town of Huntingdonshire, 68 miles north of London, and 12 north-east of Huntingdon. It is situated as it were in an island, being everywhere encompassed with fens, except on the west, where it is separated from the *terra firma* by a causeway for two miles. The neighbouring meers of Ramsey and Whittlesey, which are formed by the river Nyne, abound with fowl and fish, especially eel and large pikes. It was once famous for a very rich abbey, part of the gatehouse of which is still standing, and a neglected statue of Ailwin; the epitaph of whose tomb, which is reckoned one of the oldest pieces of English sculpture extant, styles him "kinsman of the famous King Edward, alderman of all England, and the miraculous founder of this abbey." It was dedicated to St Dunstan, and its abbots were mitred, and sat in parliament; and so many kings of England were benefactors to it, that its yearly rents, says Camden, were 7000 l. The town was then called *Ramsey the Rich*; but by the dissolution of the abbey it soon became poor, and even lost its market for many years, till about 185 years ago it recovered it. It is held on Saturday, and is reckoned one of the most plentiful and cheapest in England. In the year 1721 a great number of Roman coins were found here, supposed to have been hid by the monks on some incursion of the Danes. There is a charity school in the town for poor girls. W. Long. o. 19. N. Lat. 52. 26.

RAMSEY, an island of south Wales, on the coast of Pembrokehire, about two miles in length, and a mile and a half broad. Near it are several small ones, known by the name of the *bishop and his clerks*. It is four miles west of St David's, and 17 north-west of Milford haven. It belongs to the bishopric of St David's, and was in the last age, says Camden, famous for the death of one Justinian, a most holy man, who retiring hither from Brittany, in that age rich in saints, and devoting himself entirely to God, lived a long while in solitude, and being at last murdered by his servant was enrolled among the martyrs. W. Long. 5. 20. N. Lat. 51. 55.

RAMSEY, in the Isle of Man, to the north, a most

noted and spacious haven, in which the greatest fleet may ride at anchor with safety enough from all winds but the north-east, and in that case they need not be embayed. This town standing upon a beach of loose sand, or shingle, is in danger, if not timely prevented, of being washed away by the sea.

RAMSGATE, a sea-port town of Kent, in the isle of Thanet, five miles from Margate, where a very fine pier has been lately built for the security of ships that come into the harbour, being seated near the Downs, between the north and south Foreland, 10 miles north-east of Canterbury. The town is situated in the cove of a chalky cliff. It was formerly but an obscure fishing village, but since the year 1688 has been improved and enlarged by a successful trade to Russia and the east country. But what renders it most worthy of notice, and attracts multitudes of strangers, is the new harbour, which is one of the most capacious in England, if not in Europe. It was begun in the year 1750, but delayed by various interruptions. It consists of two piers; that to the east is built wholly of Purbeck stone, and extends itself into the ocean near 800 feet before it forms an angle; its breadth on the top is 26 feet, including a strong parapet wall, which runs along the outside of it. The other to the west is constructed of wood as far as the low-water mark, but the rest is of stone. The angles, of which there are five in each pier, consist of 160 feet each, with octagones at the end of 60 feet diameter, leaving an entrance of 200 feet into the harbour, the depth of which admits of a gradual increase of 18 to 36 feet. E. Long. 1. 30. N. Lat. 51. 22.

RAMTRUT, a deity worshipped by the Ranazins of Hindostan, where he has a celebrated temple at Onor. He is represented as more resembling a monkey than a man.

RAMUS, in general, denotes a branch of any thing, as of a tree, an artery, &c. In the anatomy of plants it means the first or lateral branches, which go off from the petiolum, or middle rib of a leaf. The subdivisions of these are called *furculi*; and the final divisions into the most minute of all, are by some called *capillamenta*; but both kinds are generally denominated *furculus*.

RAMUS (Peter), was one of the most famous professors of the 16th century. He was born in Picardy in 1515. A thirst for learning prompted him to go to Paris when very young, and he was admitted a servant in the college of Navarre. Spending the day in waiting on his masters, and the greatest part of the night in study, he made such surprising progress, that, when he took his master of arts degree, he offered to maintain a quite opposite doctrine to that of Aristotle. This raised him many enemies; and the two first books he published, *Institutiones Dialecticæ*, and *Aristotelicæ Animadversiones*, occasioned great disturbances in the university of Paris: and the opposition against him was not a little heightened by his deserting the Romish religion, and professing that of the Reformed. Being thus forced to retire from Paris, he visited the universities of Germany, and received great honours wherever he came. He returned to France in 1571, and lost his life miserably in the horrid massacre of St Bartholomew's day. He was a great orator, a man of universal learning, and endowed with very fine moral qualities.

Ramus. ties. He published many books, which Teissier enumerates. Ramus's merit in his opposition to Aristotle, and his firmness in undermining his authority, is unquestionably great. But it has been doubted, and with much reason, whether he was equally successful in his attempts after a new logical institute. We have the following general outline of his plan in Dr Enfield's History of Philosophy. "Considering dialectics as the art of deducing conclusions from premises, he endeavours to improve this art, by uniting it with that of rhetoric. Of the several branches of rhetoric, he considers invention and disposition as belonging equally to logic. Making Cicero his chief guide, he divides his treatise on dialectics into two parts, the first of which treats of the invention of arguments, the second of judgments. Arguments he derives not only from what the Aristotelians call middle terms, but from any kind of proposition, which, connected with another, may serve to prove any assertion. Of these he enumerates various kinds. Judgments he divides into axioms, or self-evident propositions, and *dianoëa*, or deductions by means of a series of arguments. Both these he divides into various classes; and illustrates the whole by examples from the ancient orators and poets.

"In the logic of Ramus, many things are borrowed from Aristotle, and only appear under new names; and many others are derived from other Grecian sources,

particularly from the dialogues of Plato, and the logic of the Stoics. The author has the merit of turning the art of reasoning from the futile speculations of the schools to forensic and common use; but his plan is defective in confining the whole dialectic art to the single object of disputation, and in omitting many things, which respect the general culture of the understanding and the investigation of truth. Notwithstanding the defects of his system, we cannot however, subscribe to the severe censure which has been passed upon Ramus by Lord Bacon and others; for much is, we think, due to him for having with so much firmness and perseverance asserted the natural freedom of the human understanding. The logic of Ramus obtained great authority in the schools of Germany, Great Britain, Holland, and France; and long and violent contests arose between his followers and those of the Stagyrice, till his fame vanished before that of Descartes."

RAN, in the old English writers, means open or public robbery, so manifest as not to be denied. *Ran dicitur aperta rapina quæ negari non potest.* Lamb. 125. Leg. Canut. cap. 58. Hence it is now commonly said of one who takes the goods of another injuriously and violently, that he has taken or snatched all he could *rap* and *ran*.

RANA, or **RANULA**. See **RANULA**.

THE following Vindication of the Character of George Fox, from the Account given of him in the Encyclopædia, Vol. XV. page 734, was drawn up by the Society called Quakers, and is now printed by their *particular Desire*.

To the Editor of the American Edition of the Encyclopædia, wherein is revived a stale, and, heretofore fully refuted Calumny, traducing the religious Character of George Fox, called by a subjoined Note, in the confident Style of authentic History, an Extract from the Works of Lesley; the following Remarks and Quotations are respectfully offered; whereby an Opportunity may be afforded his Readers of judging for themselves what Degree of Credit is respectively due to Accounts so essentially opposite; and that thereby he may disclaim any injurious Partiality having influenced him in the Republication of said Extract.

THAT national and political religion has been, and continues to be, mingled with human inventions and traditions, adapted and subservient to the purposes of lucre, and an imperious domination over the consciences of men, is evident from its recourse to a precarious intolerant coercion for support, through the vicissitudes of human power and authority. The annals of the Stewarts and of Cromwell abound with proofs of a venal priesthood, and their bigoted adherents, recurring to human depravity as an engine to uphold their systems of dead works, and maintain their usurpation of the divine prerogative: many are the instances to be found on record of those sinister pretenders to zeal for religion, exerting all their influence with the populace to excite them to tumultuous acts of violence and cruelty against innocent men and women, who were eminent examples of piety and virtue, because they believed it their duty to bear testimony to a free Gospel ministry, uninfluenced by the fordid motives of earthly emolument, and manifested their love of their neighbour by affectionately and fervently inviting them to an inward attention to the vital principle of true religion, imparted to the mind of every rational creature; boldly declaring and publishing their faith (confirmed by undeniable Scripture testimony) in this pure emanation of the Divine Nature, as the only infallible teacher, and sure guide to felicity: for this their benevolent and active zeal in asserting and disseminating those truly Christian doctrines, and for their unshaken adherence thereto, exemplified in a godly cir-

cumspection of life, and plain simplicity of manners and communication, misunderstood as a clownish singularity; they were by bigots to the vain and licentious customs prevalent in the world, accounted (as were for like reasons, the primitive followers of Christ) pestilent disturbers, and turners of the world upside down, their religion being irreconcilable to that which, through the devices of un sanctified wisdom, is modelled and accommodated to favour the ambitious aims and selfish views of those whose minds the god of this world hath blinded, who as they could not comprehend, or were unwilling to become subject to the inspeaking divine law of truth and righteousness, which those unmodified innocents bore witness to, so their pride could not endure, but took high offence at the unflattering, though really inoffensive plainness of the language and demeanor of those patient and steadfast examples and promoters of good will to men. Hence the many unmerited reproaches, scornful epithets, and nicknames, among which that of Quakers was early bestowed on this people; their practical adherence to Gospel principles made a subject of scoff and ridicule; the phrases or modes of expression used by some of the illiterate among them, perverted to the purposes of abuse and slander. Of this complexion are the generality of aspersions cast on George Fox, one of which, claiming special notice on the present occasion, is a fabrication attributed to one Lesley, reputed author of a publication entitled *The Snake in the Grass*. From this writer's works is said to be extracted, a letter from George Fox to Oliver Cromwell, a palpable perversion; of which, were there no other proofs, a candid comparison of it with the general tenor of George Fox's writings, carefully preserved, might sufficiently convince the unprejudiced of its being a piece of mockery, intended to discredit the religious principles of the people called Quakers, thro' a mimicry of the style of George Fox, and making use of some of the expressions contained in his genuine letter to Oliver Cromwell, of which this forgery is pretended to be a copy. The true purport of said genuine letter, with the circumstances leading to, and accompanying it, as cited from unimpeachable authority, by J. Gough in his *History of the People called Quakers*, Vol. I. p. 155. being as follows:

"He (George Fox) went from Drayton to Leicestershire, and from thence to Whetstone, where a meeting was to be held; but before it began, about seventeen troopers of Colonel Hacker's regiment took him up and

and brought him before the Colonel and his company of officers, by the procurement of the priests, as he thought; and after much discourse and reasoning with them, the Colonel gave him liberty to go home, provided *he would stay there and not go abroad to meeting*; but George being unwilling to agree to the conditions, his son Nedham said, 'Father, this man hath reigned too long, it is time to have him cut off.' So malicious a speech drew from George this pertinent querie; 'For what? What have I done? Or who have I wronged from a child? In this country I had my birth and education, and who can accuse me of any evil from my infancy to this day?' Then the Colonel asked him if he would go home, and stay at home? George, looking upon this requisition as unreasonable, having administered no cause for such restriction of his liberty, replied, *if he should agree thereto it would imply that he was guilty of something for which his home was made his prison: and if he went to meeting, they would consider that as a breach of their order; therefore he plainly told them he should go to meeting, and could not answer their requirings.* 'Well then,' said Hacker, 'I will send you tomorrow morning by 6 o'clock to my lord Protector, by Captain Drury, one of his life guard.' That night he was kept in the Marshalsea, and next morning about the hour appointed delivered to Captain Drury. But before they set off, requesting to speak with Colonel Hacker, he was taken to his bedside, when the Colonel repeated his order to him to go home and stay there: and George being still unwilling to comply, the Colonel insisted on his going to the Protector. Whereupon George kneeled down at his bedside and prayed the Lord to *forgive him*: looking upon him to be like Pilate, willing to wash his hands while he complied with the instigations of the persecuting priests; and therefore desired him, *when the day of his misery and trial came upon him, then to remember what he had said to him* (A.) So parting from him, he was carried prisoner by Captain Drury to London, where, being lodged at the Mermaid, Charing Cross, Drury went to inform the Protector, who sent him back with this message, that the Protector required of George Fox that he should promise not to take up the sword, or any other weapon, against him or the government, as it then was; that he should write it in what words he saw proper, and set his hand to it. George, on consideration thereof, wrote to the Protector the next morning by the name of Oliver Cromwell, declaring in the presence of the Lord, that he did deny the wearing or drawing of a sword, or any outward weapon against him or any man. That he was sent of God to stand a witness against all violence, and against the works of darkness; and to bring people from the occasion of wars and fightings to the peaceable Gospel; and from being evil doers, to whom the magistrates' sword should be a terror; to which he subscribed his name and gave it to Captain Drury to deliver to Cromwell. Some time after Drury returned, and brought George Fox before the Protector at Whitehall. Upon his coming in he said, Peace be in this house; and exhorted the Protector *to keep in the*

fear of God, that he might receive wisdom from him; that by it he might be ordered, and with it might order all things under his hand to God's glory. They had much discourse about religion, in which the Protector carried himself with much moderation: but remarking that *George Fox and his friends quarreled with the ministers.* George told him he did not quarrel with them, but they quarreled with him; but, added he, if we own the prophets, Christ, and the apostles, we cannot uphold such teachers as they testified against, that is, such as violate Christ's commands in not giving freely; such as take the oversight of the flock for filthy lucre and divine for money. When George made a motion to retire, upon other people coming in, Cromwell took him by the hand, and with tears in his eyes said, Come again to my house, for if thou and I were but an hour of a day together, we should be nearer one to another; adding, that he wished him no more ill than he did his own soul. Then George bade him hearken to the voice of God, stand in his counsel and obey it, if he did so it would preserve him from hardness of heart, but if not, his heart would be hardened. The Protector seemed affected, and said it was true. George then taking his leave retired, and Captain Drury following him out, informed him that the Lord Protector said he was at liberty, and might go whither he would."

The adversaries of this religious society manifested a peculiar enmity against George Fox, and to their own degradation, in not a few instances, alleged things respecting him, both absolutely false and grossly absurd (B). By such practice and defamations he appears to be considered a wild fanatic and mad enthusiast, by those who knew little of him, and had little inclination to be better informed, willing to abide under prejudice rather than listen to any thing tending to remove it; while those who knew him best, and are most to be depended on for a true account of him, do testify that he had a fair, reasonable, and equitable claim to the apostle's defence—"I am not mad; but speak forth the words of truth and soberness."

Joseph Phipps, in his book entitled *The Original and Present State of Man*, &c. page 162. in answer to the ill-founded cavils of S. Newton against George Fox, gives the following account of him, the *veracity* whereof is presumed to be supportable by more authentic testimonials than any his vilifiers can substantiate.

"The fundamentals he preached were, Christ once in the flesh, and always in spirit, as the light and life of men, the Mediator, the Propitiation, the Intercessor, the potential and actual Redeemer, offered for all, and to all, and the especial Saviour of all that believe in him so as to obey him; with the necessity of regeneration in man, and the practice of every moral and Christian virtue.

"Is it nothing extraordinary, that a person so obscure and illiterate, so little conversant amongst men, so uneducated in arts, languages, and sciences, so unversed in the various modes of divinity, by turns in fashion,

(A) Which he did when near his execution, being tried and condemned in 1660, as one of the judges of King Charles I.

(B) The sorry fictions of Marshall afford a sample in kind. See Gough's History, Vol. I. p. 119.

fashion, uninstructed, unprovided, unprotected by men, should singly and alone launch into the troubled sea of a tempestuous fluctuating world, and in direct opposition to all the pride, policy, and power of a learned and lucrative priesthood, and a prejudiced people with a bigoted magistracy at their head; that such an one, by the simple doctrine of the cross of Christ, should be made instrumental to the turning of thousands, not from form to form, but from darkness to light; from the power of Satan to the power of God; from a death in sin, to a life of righteousness; from habitual vice, to a course of virtue, inasmuch that some judicious magistrates declared, the people raised through his ministry, eased their hands of much trouble; and had it not been for the spreading of this principle of divine light, the nation would have been overrun with rantism and licentiousness. In this great and good work, George Fox, with the people he had been instrumental to raise, stood with unabated courage and constancy, and were enabled, with undaunted fortitude to bear up against near forty years cruel persecution, with small intervals, both from royal and republican parties, as each ascended the scale of national power. This he was favoured to see an end of, before his removal beyond the noise of archers, and out of the reach of envy and malignity."

The same author, page 209. shewing said Newton's false citation from George Fox's Great Mystery, and perversion of his true meaning, adds,

"George Foxes Treatise was printed in 1659, and contains cursory answers to above an hundred different opposers, who in a manner mobbed him from the press at that contentious period; and as he had full employment for his time otherwise, and had not the benefit of that literature which is now common, infamous advantages then were, and have often since been taken by designing antagonists, of the inaccuracy of his expressions. But I should think it beneath any person of a liberal education and character, to copy from those ill-intenders, or to follow them in such a disingenuous line."

In point of veracity, and intimate knowledge of the true, rational, moral, and religious character of George Fox, it is presumed that, amongst his revilers, or those who shew a fondness for reviving their calumnies, no authority can be produced which, with judges ingenuous of temper and upright of meaning, will be held more unquestionably respectable than that of William Penn, who in his Preface to George Fox's Journal, folio 30. gives this testimony of him:

"Truly I must say, that though God had visibly clothed him with a divine preference and authority; and indeed his very presence expressed a religious majesty, yet he never abused it, but held his place in the church of God with great meekness, and a most engaging humility and moderation. For upon all occasions, like his blessed Master, he was a servant to

all, holding and exercising his eldership in the invisible power that had gathered them, with reverence to the head and care over the body, and was received only in that spirit and power of Christ, as the first and chief elder of his age; who as he was therefore worthy of double honour, so for the same reason it was given by the faithful of this day, because his authority was inward and not outward, and that he got it and kept it by the love of God and power of an endless life. I write my knowledge and not report, and my witness is true, having been with him for weeks and months together on divers occasions, and those of the nearest and most exercising nature, and that by night and by day, by sea and by land, in this and in foreign countries; and I can say I never saw him out of his place or not a match for every service or occasion. For in all things he acquitted himself like a man, yea a strong man, a new and heavenly-minded man. A divine, and a naturalist, and all of God Almighty's making. I have been surprised at his questions and answers in natural things, that whilst he was ignorant in useless and philosophical science, he had in him the foundation of useful and commendable knowledge, and cherished it every where. Civil beyond all forms of breeding in his behaviour; very temperate, eating little and sleeping less, though a bulky person."

Such is the clear, unambiguous account given of this grossly-abused, much-enduring servant of Jesus Christ; not only by William Penn, but also by other his cotemporaries, nearly intimate and thoroughly acquainted with him.

Terms of scoff and derision are not uncommon with those who have no better authority for their envious declamation; thus we find in the paragraph following the extract from Lesley, the scornful addition of senseless enthusiast tacked to the name of George Fox; but where does there appear any ground for such imputation? Will it be alleged that it is amply shewn in that curious preceding fabrication? If that be admitted a true copy of George Fox's letter to Oliver Cromwell, it affords ample ground indeed; but that forgery detects itself: Who, acquainted with the history and spirit of those times, must not be convinced that George Fox, setting his name to such a compound of blasphemous absurdity, could not have escaped a very cruel punishment. Were not the adversaries of the despised people called Quakers industriously seeking occasion for criminating them? and against George Fox peculiarly, for want of real matter of offence, were not despicable frauds practised? Let those who wish not to be imposed on, search, like the noble Bereans, and satisfy themselves of truth and fact (c).

The bold assertion that a number of learned and ingenious men, joining the Quakers, new modelled their creed, is totally destitute of support from any creditable authority. That men of piety and ability defended and illustrated the doctrines and tenets taught and

(c) See Gough's History, Vol. I. p. 122. Recital of a formidable combination by procurement of false witnesses, to convict George Fox of blasphemy. The account likewise which this author gives in the same volume, page 80, of the occasion of disgust against the people called Quakers, has a claim to the attention of honest inquirers, as has his citations from divers detractors, with his remarks thereon, shewing their partial and disingenuous colouring, particularly from D. Neal's works, p. 83. 85. 96. 354—357. Mosheim's illiberal misrepresentations also cited and exposed—same book, p. 100. 249.

and published with indefatigable diligence and unquerable patience by George Fox, is undeniably true. What were in those doctrines and tenets, unconformable to the true *Christian standard*? What did they contain that could *shock common sense*, unless it were the common sense of bigots to an earthly, political form of religion, from which they sought worldly exaltation and gain?

The religious principles originally professed and practically adhered to by George Fox and his fellow labourers, under the influence of Gospel love, have continued and remain, without variation, the principles of the people called Quakers to this day.

George Fox, deeply *learned* in the knowledge of things spiritual and divine, though not *ingenious* in the artificial arrangement of words and sentences, was peculiarly exercised in arduous endeavours to excite to such an introversion of mind as might, under divine favour, afford a sight and sense of the heavenly efficacy of the grace of God, in its saving and purifying operation; the universality and sufficiency whereof he

earnestly contended for, as *the faith once delivered to the saints*: consistent and harmonizing with this great fundamental, as its natural branches, are the tenets professed, and testimonies borne, by George Fox, with whom therein the people called Quakers have ever been, and continue united; any work or contrivance of *learned ingenious men*, by them as a religious body, owned, to *new model* this *creed*, cannot be made appear: such pretended reform, therefore, attributed to human learning and ingenuity (by some so much preferred to the salutary work of divine grace) is a mere arbitrary, unfounded assumption. How the writer of this paragraph came by his account, which is a direct falsehood, that *G. Keith was excommunicated for the liberties he took with the great apostle* (if George Fox be thereby meant) will be proper for him or his adherents to shew; how, or in what instance, *Keith's writings contributed to the moderation of Penn*, or to the elegant and masterly *Apology of Barclay*, is left to be made out by the learning and ingenuity of the same writer.

*Signed on behalf and by direction of a meeting of the
representatives of the religious society called Quakers,
held in Philadelphia, 15th 12 month, 1796,*

JOHN DRINKER, CLERK.
